**FORT DEVENS
SITE INVESTIGATION REPORT****ANALYTICAL DATA QUALITY REPORT****E.1.0 INTRODUCTION**

Data quality evaluations for off-site laboratory data collected during the 1992 SI, and 1993 SSI for Groups 2 and 7 are presented in this Appendix. Soil, sediment, and groundwater samples were collected during both field events.

Soil, sediment, and groundwater samples collected during the SI and SSI were analyzed in a USAEC performance demonstrated laboratory for Fort Devens Project Analyte List (PAL) analytes. Off-site laboratory analyses for the PAL organics and inorganics are considered approximately equivalent to USEPA analytical support Level III quality data.

Soil and groundwater samples were also analyzed in the field during the SI and SSI. Target analytes for these programs are presented in Section 3.0.

A list of USAEC performance demonstrated methods used by ESE during each phase are provided in Table E1. The table includes a description of the methods used as well as equivalent EPA methods, where they exist. All methods were performed by ESE using the 1990 USATHAMA QA Plan (USATHAMA 1990). The method numbers (i.e., method JS16) are specific to the method and to the particular laboratory doing the analyses. As described in Section 3.2.3, the laboratory must document proficiency using each of the methods by meeting strict USAEC performance protocols. Once the laboratory has demonstrated proficiency, they become qualified to perform that particular method. It is through this performance demonstration process that certified reporting limits (CRLS) were established. CRLs for particular compounds and elements are presented in Tables E2 through E8.

Section 2.0 of this Appendix presents results of off-site laboratory method blank and field QC blank (field blanks, rinse blanks, and trip blanks) results. The information presented on analytes detected in blanks was used to identify potential false positive contaminants in contamination assessments presented in this Revised SI Report.

ABB Environmental Services, Inc.

APPENDIX E

Data for field programs conducted in 1992 and 1993 are presented in separate subsections.

Section 3.0 of this Appendix presents results from matrix spike (MS) and field duplicate analyses. MS and field duplicate results are used to access the accuracy and precision of the analytical measurements.

E.2.0 QUALITY CONTROL BLANK RESULTS

A quality control review was completed for method blanks, rinsate blanks and trip blanks associated with off-site analytical samples collected from Groups 2 and 7 SAs. Quality control blank from the 1992 SI and 1993 SSI field events are evaluated. The goal of this discussion is to provide data from method and field quality control blanks to be used to identify possible field sampling or off-site laboratory related contaminants which have been reported in the results for samples collected from the Groups 2 and 7 SAs.

E.2.1 LABORATORY METHOD BLANKS

Method blanks were analyzed at the off-site laboratory with each lot of samples to evaluate if sample processing and analysis resulted in contamination of samples. Both water and soil matrices were used for this evaluation. Method blanks were sorted by lot number. Those lots that correspond to samples collected during the SI and SSI were included in the method blank assessment. Method blanks were analyzed for USAEC analytical methods for the following chemical classes of analytes: inorganics, VOCs, SVOCs, pesticides, PCBs, certified wet chemistry procedures, and explosives. Other analyses employed standard USEPA methods (USEPA, 1983) including TDS, TSS, alkalinity, TOC, hardness and TPHC.

E.2.1.1 1992 SI

Method blanks were performed on both water and soil samples using the following methodologies: inorganics in water and soil (USAEC Methods SB01, SD09, SD20, SD21, SD22, SD28, SS10, JB01, JD15, JD17, JD19, JD24, JD25, JS16), VOCs in water and soil (USAEC Methods UM20 and LM19), SVOCs in water and soil (USAEC Methods UM18 and LM18), pesticides in water and soil (USAEC Methods UH13 and LH10), PCBs in water and soil (USAEC methods UH02 and

ABB Environmental Services, Inc.

APPENDIX E

LH16), explosives in water and soil (USAEC Methods UW32, UW19 and LW12), nitrate/nitrite as nitrogen in water (USAEC Method TF22), total Kjeldahl nitrogen (USAEC Method TF26), total phosphate in water (USAEC Method TF27), and chloride/sulfate ion in water (USAEC Method TT10). Other analyses that were employed using standard USEPA methods include TSS, alkalinity, TOC, hardness and TPHC. Method blank data from the 1992 Fort Devens SI are presented in Table E9.

Inorganics. Two aqueous method blanks were analyzed by the laboratory for the detection of inorganics in water. Forty seven of forty eight (98%) possible results were below the Certified Reporting Limit (CRL). Lead was detected in one blank at 3.2 µg/L.

Twelve of a possible twenty-six results (46%) were reported at below CRLs. Elements detected in the soil are summarized below:

ELEMENT	CRL (µg/g)	REPORTED CONCENTRATION (µg/g)
Al	2.35	1300
Ba	5.18	9.0
Ca	100	11700
Cr	4.05	4.8
Cu	0.965	1.9
Fe	3.68	1770
K	100	330
Mg	100	1660
Na	100	3040
Pb	1.71	1.79
Zn	8.03	9.1

Soil method blanks analyses were conducted by the laboratory using a USAEC approved soil as the matrix. A Tampa Bay soil type was used. The high frequency

APPENDIX E

and concentrations of many of the inorganics are due to background levels inherent in this soil type. These results are not interpreted to be indicative of gross laboratory contamination. Based on aqueous method blank analyses the laboratory was free of introduced inorganic contamination.

VOCs. Two water method blanks were analyzed for VOC contamination by Method UM20. Seventy-five of seventy-eight (96%) possible aqueous VOC results were concentrations below CRLs. Two compounds, methylene chloride and chloroform, were detected above the CRL. Methylene chloride was reported at 4.6 $\mu\text{g}/\text{L}$ in one aqueous method blank. Chloroform was detected in both water method blanks at 0.91 and 1.1 $\mu\text{g}/\text{L}$. Methylene chloride is a solvent used frequently by commercial laboratories. Chloroform is a compound frequently produced in chlorinated drinking water supplies. Chloroform and methylene chloride are likely present as a result of laboratory contamination.

Four soil method blanks were analyzed for VOCs by Method LM19. One hundred thirteen of one hundred seventeen (97%) possible soil VOC method blank results were concentrations below CRL. Three VOCs were found at low concentrations in the soil method blanks. These are acetone, trichlorofluoromethane, and chloroform. Acetone and trichlorofluoromethane were reported in one of the four soil method blanks. Acetone was detected at 0.027 $\mu\text{g}/\text{g}$ and trichlorofluoromethane was detected at 0.008 $\mu\text{g}/\text{g}$. Both of these compounds are considered by the USEPA to be common laboratory contaminants (USEPA 1991). Chloroform was detected in two of four soil method blanks. The concentrations at which chloroform was reported were 0.001 $\mu\text{g}/\text{g}$ and 0.002 $\mu\text{g}/\text{g}$. The blank results indicate that low concentrations of chloroform, acetone and trichlorofluoromethane reported in samples may have been introduced during laboratory handling.

SVOCs. Method blanks were analyzed to determine whether SVOC compounds were introduced during the sample preparation process. Soil and water blanks were prepared using Methods LM18 and UM18, respectively.

Three aqueous method blanks were analyzed for SVOC contamination. Two hundred ninety of two hundred ninety-one (99%) possible results were concentrations below CRLs. The only compound detected in any of the three method blanks was bis(2-ethylhexyl)phthalate. It was detected in one water method blank at 6.0 $\mu\text{g}/\text{L}$. Bis(2-ethylhexyl)phthalate is considered by the USEPA to be a common laboratory

APPENDIX E

contaminant (USEPA, 1991). Sample results with similar concentrations of bis(2-ethylhexyl)phthalate may represent laboratory contamination.

Three soil method blanks were analyzed for SVOC contamination. Two hundred ninety-one of the two hundred ninety-two (99.6%) possible SVOC results were concentrations below CRLs. The only SVOC compound detected was di-N-butyl phthalate. Di-N-butyl phthalate was detected in one blank out of three at 0.09 µg/g. Di-N-butyl phthalate belongs to the family of phthalate esters identified by the USEPA as common laboratory contaminants.

Pesticides/PCBs. Three aqueous method blanks were used to determine if pesticide or PCB compounds were introduced during laboratory preparation and handling. One hundred percent of the aqueous pesticide/PCB method blank results were concentrations below CRL values.

Three soil method blanks were analyzed for pesticide/PCB contamination. Fifty-five of fifty-eight (95%) possible results were concentrations below CRL values. Compounds which were detected using method LH10 included the pesticides alpha-chlordane, gamma-chlordane and heptachlor. All three detected pesticide compounds were reported at a frequency of one of three soil method blanks. The concentrations at which each of the pesticides were detected are as follows: alpha-chlordane at 0.006 µg/g, gamma-chlordane at 0.041 µg/g, and heptachlor at 0.032 µg/g. The concentrations reported for these compounds represent low-level contamination that was either present in the soil media used for the method blank or was introduced during laboratory activities. All detections for these compounds occurred in the lot AVB. These compounds were not detected in samples from this lot.

Explosives. One aqueous method blank was analyzed for explosive compounds using USAEC Method UW32. No explosive analytes were detected above CRLs. In addition, two aqueous method blanks were analyzed for PETN and nitroglycerine using USAEC Method UW19. All results for this analysis were below CRLs. One soil method blank was analyzed for explosive compounds using USAEC Method LW12. No explosive analytes were detected above CRL. Both soil and water method blank data indicate that concentrations of explosive compounds were not influenced by laboratory activities.

APPENDIX E

Nitrites/Nitrates as Nitrogen and Total Kjeldahl Nitrogen. Two method blanks were analyzed in association with nitrate/nitrite and Kjeldahl nitrogen water samples. One hundred percent of the concentrations reported for both analyses were below CRL. This indicates that sample concentrations for nitrate/nitrite as nitrogen and Kjeldahl nitrogen were not influenced by laboratory activities.

Phosphates. One water method blank was analyzed for concentrations of phosphates. The concentration of phosphate for this blank was reported at below CRL. This indicates that phosphate ion concentrations in sample results were not influenced by laboratory activities.

Chloride/Sulfate Ions. Two method blanks were analyzed for chloride and sulfate ion laboratory contamination. One hundred percent of the sulfate and chloride ion concentrations reported for these blanks were below CRLs. This indicates that sample results for these parameters were not influenced by laboratory activities.

USEPA Methods. Method blanks were analyzed for the following USEPA methods (USEPA, 1983): TSS, hardness, alkalinity, TOC and TPHC.

One water method blank was analyzed in association with TSS samples. The concentration reported for this blank was below the laboratory reporting limit (RL) of 4000 $\mu\text{g}/\text{L}$.

Two water method blanks were analyzed for hardness. Blanks concentrations were below the RL of 1000 $\mu\text{g}/\text{L}$.

Two water method blanks were analyzed for alkalinity. Both blanks had concentrations below the RL of 5000 $\mu\text{g}/\text{L}$.

One soil method blank was analyzed for TOC. The TOC concentration for this blank was below the RL of 100 $\mu\text{g}/\text{L}$.

TPHC analysis was completed for three soil method blanks and two water method blanks. One hundred percent of the soil method blank results were concentrations below the RL of 20 $\mu\text{g}/\text{g}$. Both water method blank results were below the RL of 200 $\mu\text{g}/\text{L}$.

E.2.1.2 1993 SSI

Method blank results for the 1993 Fort Devens SSI are found in Table E10 of this appendix. Method blanks included in this table were sorted by lot number. Only those lots that correspond to samples collected during the 1993 Fort Devens SSI were included. This assessment also includes method blanks associated with samples collected during both rounds of groundwater sampling. Method blanks were analyzed for USATHAMA Methods for the following chemical classes of analytes: inorganics, VOCs, SVOCs, pesticides/PCBs, explosives, nitrate/nitrite as nitrogen, total Kjehldahl nitrogen, anions and phosphates. Other analyses that were employed using standard USEPA Methods include TDS, TSS, HCO₃, alkalinity, TOC, hardness and TPHC.

Inorganics. Inorganic method blank analyses were completed for PAL elements: A total of one hundred seventy-eight results were obtained for all elements. One hundred seventy-seven of one hundred seventy-eight element results (99%) were at concentrations below established CRL values. The only element detected in any of the method blanks was iron at 56 µg/L. This detection was associated with lot # ZFUA. The method blank data indicate that there was minimal laboratory contamination during the execution of the aqueous inorganic methods.

Soil method blanks were analyzed for the same elements as the aqueous method blanks. Three soil method blanks were used for analysis of all elements. Forty-five of sixty-nine (61%) inorganic soil results were below the CRL. Elements which were detected above CRL are summarized below:

Element	CRL (µg/g)	Frequency Detected Above CRL	Reported Concentration Range (µg/g)
Aluminum	2.35	3/3	336-584
Barium	5.18	3/3	7.0-9.5
Calcium	100	3/3	697-849
Iron	3.68	3/3	729-955
Potassium	100	3/3	101-150
Lead	0.177	3/3	0.37-0.61
Magnesium	100	3/3	213-273

APPENDIX E

Element	CRL ($\mu\text{g/g}$)	Frequency Detected Above CRL	Reported Concentration Range ($\mu\text{g/g}$)
Manganese	100	3/3	17-33
Sodium	100	3/3	212-275

Soil method blanks analyses were conducted by the laboratory using a USAEC approved soil as the matrix. This soil type is described as a Tampa Bay soil. The high frequency and concentrations of many of the inorganics are believed to be due to background levels inherent in this type of soil. These results are not interpreted to be indicative of gross laboratory contamination. Based on aqueous method blank analyses the laboratory was free of introduced inorganic contamination.

VOCs. Method blanks were run with each lot of water and soil samples to determine if VOCs were introduced during sample preparation and handling at the laboratory.

Twenty-four water method blanks were analyzed for VOCs. Nine hundred twenty eight of nine hundred thirty-six (99%) VOC concentrations were below CRLs. Compounds reported above CRL include acetone, chloroform, methylene chloride and methyl ethyl ketone (2-butanone). Acetone was reported in three method blanks (lots ICFA, ICLA, XDOB) at concentrations ranging from 16 $\mu\text{g/L}$ to 53 $\mu\text{g/L}$. Methylene chloride was also reported in three method blanks (lots GBOA, XDOB, XDPB) at concentrations ranging from 6.9 to 9.1 $\mu\text{g/L}$. Acetone and methylene chloride are often used as solvents at commercial laboratories. Methyl ethyl ketone was reported in one blank (lot GBOA) at 9.5 $\mu\text{g/L}$. Methyl ethyl ketone is defined by the EPA as a common laboratory contaminant. Chloroform was detected in one method blank at a concentration of 1.1 $\mu\text{g/L}$. Chloroform is often produced in chlorinated drinking water supplies. Chloroform and all of the other detected VOCs are likely to have been introduced as contaminants at the laboratory.

Eleven soil method blanks were analyzed for VOC contamination. One hundred percent of the four hundred twenty-nine results were concentrations below the CRLs. There was no laboratory contamination of VOCs observed for the soil method blanks.

APPENDIX E

SVOCs. Thirteen water method blanks were analyzed for ninety-seven SVOCs. One thousand two hundred fifty of one thousand sixty-one (99%) possible results were concentrations less than CRLs. Compounds detected in the water method blanks are summarized below:

COMPOUND	FREQUENCY OF DETECTION	ASSOCIATED LOTS	CONCEN. RANGE ($\mu\text{g}/\text{L}$)
1,2-Epoxyhexane	4/13	CKMA, WDYA, WDBB, WDFB	1.0 - 7.0
Bis(2-ethylhexyl)phthalate	2/13	GCUA, WDYA	6.7 - 200
Mesityl oxide	1/13	WDYA	2.0
2-Cyclohexen-1-ol	1/13	WDZA	3.0
2-Cyclohexen-1-one	1/13	WDZA	4.0

1,2-epoxyhexane, mesityl oxide, 2-cyclohexen-1-ol and 2-cyclohexen-1-one were reported as TICs and are not target analytes. These compounds are often used as preservatives in solvents such as methylene chloride. All of these compounds are defined by the USEPA as laboratory contaminants (USEPA 1991). Another detected SVOC, bis (2-ethylhexyl)phthalate, is similarly defined as a laboratory contaminant by the USEPA.

Other non-target compounds which were also detected using the SVOC water method include toluene and tetrachloroethene. Toluene was detected in two method blanks at 2.0 and 3.0 $\mu\text{g}/\text{L}$. Tetrachloroethene was detected at 10 $\mu\text{g}/\text{L}$. Since quantitative data for these compounds were obtained from the VOC method, method blank data for toluene and tetrachloroethene obtained from the SVOC method were not used and likely represent traces of these VOCs in the extraction solvent.

Six soil method blanks were analyzed for SVOCs. Five hundred seventy-seven of five hundred eighty-two (99%) possible results were concentrations below CRLs. Detected contaminants include di-n-butyl phthalate and bis (2-ethylhexyl) phthalate. Di-n-butyl phthalate was detected in four of six method blanks (lots FWMA, HZFA, HZKA, HZSA) at concentrations from 0.31 to 40 $\mu\text{g}/\text{L}$ while bis (2-ethylhexyl)

APPENDIX E

phthalate was detected in one blank (lot HZKA) at 2.2 ug/g. Phthalate esters are identified as common laboratory contaminants by the USEPA.

Pesticides/PCBs. Seven water method blanks were analyzed for pesticide/PCB compounds. One hundred percent of the concentrations were below corresponding CRL values. Two soil method blanks were analyzed for pesticide/PCB contamination. One hundred percent of the concentrations were below CRLs. There was no evidence of laboratory contamination of pesticide/PCB compounds in either the soil or water method blanks.

Explosives. Seven water method blanks were analyzed for explosives. One hundred percent of the results were concentrations below CRLs. Two soil method blanks were analyzed for explosives. One hundred percent of the concentrations were below CRLs. The water and soil method blank data indicate that no explosive compounds were introduced as laboratory contamination.

Nitrites/Nitrates as Nitrogen. Five method blanks were analyzed for nitrites/nitrates as nitrogen and one method blank was analyzed for total Kjeldahl nitrogen. One hundred percent of the concentrations were below CRLs for both methods.

Anions. Five method blanks were analyzed for concentrations of chloride, fluoride, and sulfate ions. One hundred percent of the results for concentrations of all anion parameters were below CRLs.

Phosphates. One method blank was analyzed for phosphate ion contamination. The concentration was reported at below the CRL of 13.3 $\mu\text{g}/\text{L}$.

USEPA Methods. Method blanks were also analyzed for the following parameters: TSS, hardness, alkalinity, TOC, TPHC and TDS. Standard EPA methods (USEPA, 1983) are used for these analyses.

Fourteen method blanks were analyzed in association with TSS samples. Ten of fourteen blanks (71%) had concentrations below the RL of 4,000 $\mu\text{g}/\text{L}$. The range of TSS concentrations for detections in the method blanks was from 4000 to 7000 $\mu\text{g}/\text{L}$. The TSS values for the lots involved (IQZA, TECG, TEKG and TEQG) are indicative of low level laboratory contamination.

One method blank was analyzed for hardness concentrations. The concentration at which hardness was reported for this blank was below the RL of 1000 $\mu\text{g}/\text{L}$.

Two method blanks were analyzed for alkalinity. Both method blanks had concentrations at below the RL of 5000 $\mu\text{g}/\text{L}$.

Six soil method blanks were analyzed for TOC. One hundred percent of the results were below the RL.

TPHC analysis was completed for five soil and nine water method blanks. One hundred percent of the soil method blanks had concentrations below the RL of 28.7 $\mu\text{g}/\text{g}$. One hundred percent of the water method blanks had concentrations below the RL of 171 $\mu\text{g}/\text{L}$. The method blank data indicate that there was no laboratory contamination for TPHC.

Five method blanks were analyzed for concentrations of TDS. Four of five (80%) results were concentrations below the RL of 10000 $\mu\text{g}/\text{L}$. The concentration at which it was detected was 12000 $\mu\text{g}/\text{L}$. The TDS detection was associated with lot TEZF.

E.2.2 FIELD QUALITY CONTROL

Field quality control blanks associated with Groups 2 and 7 which were collected during the Fort Devens SI and SSI include: field blanks, rinse blanks, and trip blanks.

E.2.2.1 Field Blanks

Prior to the commencement of field activities in 1992 and 1993, field blanks were collected. The field blank water came from a USAEC approved source at Fort Devens. This water was used throughout the SI and SSI for decontamination operations. Field blank detections for all three investigations are presented in Table E11.

Methodologies that were used to analyze the field blanks include the following: inorganics (USAEC Method SS10, SB01, SD09, SD20, SD21, SD22, SD28), VOCs (USAEC Method UM20), SVOCs (USAEC Method UM18), pesticides (USAEC Method UH13), PCBs (USAEC Method UH02), explosives (USAEC Method UW32), nitrite/nitrate as nitrogen (USAEC Method TF22), chloride/sulfate ion

ABB Environmental Services, Inc.

APPENDIX E

(USAEC Method TT10), total phosphorus (USAEC Method TF27), and total Kjeldahl nitrogen (USAEC Method TF26). Other methods which do not require USAEC certification include total TPHC, TOC, total alkalinity, TSS, phenolphthalein alkalinity, bicarbonate ion, and carbonate ion.

Inorganics. A subset of target elements were detected in field blanks at concentrations above the CRL. Elements that were detected are summarized in Table E11.

The elements, and the concentrations at which they were measured, are likely representative of inorganics inherent in New England groundwater. The results reflect background concentrations in groundwater samples collected at Fort Devens.

VOCs. All concentrations reported for VOCs in the field blanks were below respective CRLs with the exception of chloroform. A detection of 1.7 µg/L for this compound was reported in the 1993 SSI field blank. Chloroform was identified in method blank discussions (see Section E.2.1) as a laboratory contaminant.

SVOCs. The only target SVOC compound detected above the CRL in any of the field blanks was bis(2-ethylhexyl)phthalate. The concentrations at which it was detected ranged from 9.9 to 53 µg/L for an average value of 32 µg/L. Bis(2-ethylhexyl)phthalate was likely introduced as a laboratory contaminant during sample preparation.

Two non-target SVOCs were also detected in field blanks. These compounds are 2-ethyl-1-hexanol and hexanedioic acid dioctyl ester. 2-ethyl-1-hexanol was detected at 10 µg/L in one field blank collected prior to the 1993 SSI. Hexanedioic acid dioctyl ester was detected at 9.00 µg/L in one field blank collected prior to the 1992 SI.

Pesticides/PCB's. One hundred percent of the concentrations reported for pesticide/PCB compounds were below CRL values for field blanks collected during the SI and SSI.

Explosives. One hundred percent of the concentrations reported for explosive compounds were below CRLs for all field blank samples.

Nitrite/Nitrate as Nitrogen. Nitrite/nitrate expressed as nitrogen was detected in field blanks collected for the 1992 SI and the 1993 SSI. Concentrations ranged from 530 to 710 $\mu\text{g}/\text{L}$. These results may reflect background concentrations in groundwater in the vicinity of Fort Devens. TKN was not detected above the CRL of 183 $\mu\text{g}/\text{L}$.

Chloride/Sulfate Ion. Chloride ion concentrations were not reported in the 1992 and 1993 field blanks.

Total Phosphorus. Concentrations reported for phosphorus were below CRL all field blanks.

Other Methods. Analyses for TPHC, TOC, total alkalinity, TSS, phenolphthalein alkalinity, bicarbonate ion, and carbonate ion were completed for each of the field blanks. Concentrations reported for TSS, TPHC, TOC, phenolphthalein alkalinity and carbonate ion concentrations were below corresponding CRLs for all field blanks. Total alkalinity was detected at concentrations ranging from 14000 to 28000 $\mu\text{g}/\text{L}$ in field blanks associated with the 1992 SI and 1994 RI. Bicarbonate ion was detected at 34,000 $\mu\text{g}/\text{L}$ and 33,000 $\mu\text{g}/\text{L}$ in 1992 field blank samples. Hardness concentrations were detected at concentrations ranging from 17000 to 24000 $\mu\text{g}/\text{L}$ in all field blanks.

E.2.2.2 Rinse Blanks

Rinse blanks were collected by pouring previously analyzed water over sampling equipment (i.e., split spoons) and into sample containers. The purpose of collecting a rinsate blank was to determine the effectiveness of decontamination procedures in removing target analytes from sampling apparatus. Rinsate blanks were not collected during groundwater sampling of monitoring wells since there is dedicated sampling equipment for each location.

E.2.2.2.1 1992 Rinse Blanks. Rinse blank data from the 1992 field investigations at Groups 2 and 7 SAs have been tabulated and are presented in Table E12. The rinsate blanks were tested using the following methodologies: inorganics (USAEC Methods SB01, SD09, SD20, SD21, SD22, SS10), VOCs (USAEC Method UM20), SVOCs (USAEC Method UM18), pesticides (USAEC Method UH13), PCBs (USAEC Method UH02), explosives (USAEC Method UW32) nitrite/nitrate as nitrogen (USAEC Method TF22), and chloride/sulfate ion (USAEC Method TT10).

ABB Environmental Services, Inc.

APPENDIX E

Other USEPA methods include total organic carbon (TOC), and total petroleum hydrocarbons (TPHC).

Inorganics. One rinsate blank was analyzed for the majority of target inorganics. The field sample number for the rinsate is SBK92302. Three rinsates were analyzed for lead using USAEC Method SD20. The rinsates analyzed for lead included SBK92302, SBK92307, and SBK92310.

Twenty-two of twenty-five (88%) possible inorganic results were concentrations below CRL values. Potassium was detected in the rinsate SBK92302 at 488 $\mu\text{g}/\text{L}$. The CRL for potassium is 375 $\mu\text{g}/\text{L}$. The amount of potassium detected in the rinsate blank does not greatly exceed CRL indicating that a small amount of instrument contamination occurred. The detection of potassium in the rinsate blank is not believed to affect the data quality for this parameter.

Lead was detected in two of three rinsates at 2.6 and 3.4 $\mu\text{g}/\text{L}$. Lead was also detected in a method blank at a concentration of 3.2 $\mu\text{g}/\text{L}$. In addition to being detected in the method blank, lead was detected in the field blanks at an average concentration of 3.2 $\mu\text{g}/\text{L}$. Since lead was detected in the method blank and the field blank, contamination in the rinsate blank may have occurred as a result of laboratory contamination or as a result of carry over from USAEC approved water used for decontamination.

Overall, the rinsate blank data for inorganics indicate that decontamination procedures were effectively implemented.

VOCs. Three rinsate blanks were analyzed for VOCs. These blanks are SBK92302, SBK92307 and SBK92310. One hundred fifteen of one hundred seventeen (98%) possible VOC results were concentrations below the CRLs. The only detected VOC was 1,1,1-trichloroethane. 1,1,1-Trichloroethane was detected in two of the three rinsates. Concentrations of the detections were 2.5 $\mu\text{g}/\text{L}$ and 1.8 $\mu\text{g}/\text{L}$. 1,1,1-Trichloroethane was not found in method blanks or in the field blank. The maximum concentration detected, 2.5 $\mu\text{g}/\text{L}$, is well below the federal drinking water standard of 200 $\mu\text{g}/\text{L}$ for 1,1,1-trichloroethane. Concentrations of 1,1,1-trichloroethane, which are reported in samples at similar concentrations as those detected in rinsate blanks, should be considered estimated.

APPENDIX E

SVOCs. One rinsate blank was analyzed for SVOCs. This rinsate blank is SBK92302. One hundred percent of the possible ninety seven SVOC results were concentrations below CRLS. This indicates that decontamination procedures were effective in the removal of potential SVOC contamination.

Pesticides/PCBs. The rinsate blank SBK92302 was analyzed for pesticide and PCB compounds. One hundred percent of the possible twenty-nine pesticide/PCB results were concentrations below CRL values. This indicates that decontamination procedures effectively removed potential contamination of these compounds.

Explosives. The rinsate blank SBK92302 was analyzed for explosives. One hundred percent of the possible eleven explosives compound results representing both methods were concentrations below the CRLs. This indicates that decontamination processes were effective in the removal of potential contamination of explosives compounds.

USEPA Methods. Other standard USEPA methods for which rinsates were analyzed included TOC and TPHC.

Analysis for TOC was completed using three rinsate blanks. The three rinsates were SBK92303, SBK92307, and SBK92310. The rinsate SBK92307 had TOC concentrations at 1,340 $\mu\text{g}/\text{L}$. This concentration is slightly greater than the established CRL of 1,000 $\mu\text{g}/\text{L}$. The other two rinsates had TOC concentrations below the CRL. Overall, decontamination processes were successful in the removal of TOC concentrations from the sampling equipment.

Three rinsate blanks were analyzed for TPHC contamination. These rinsates include the following: SBK92302, SBK92307, and SBK92310. One hundred percent of the three TPHC concentrations were below the CRL of 200 $\mu\text{g}/\text{L}$. This indicates that TPHC contamination from the sampling equipment did not occur.

E.2.2.2.2 1993 Rinse Blanks. Three rinse blanks associated were collected at the Groups 2 and 7 SAs during the 1993 Fort Devens SSI (SBK93686, SBK93124, SBK93721). The rinsate blanks were tested for some or all of the following chemical parameters: inorganics, VOCs, SVOCs, explosives, pesticides/PCBs, nitrite/nitrate as nitrogen and chloride/sulfate ion. Other standard USEPA methods performed include alkalinity, bicarbonate ion, TOC, and TPHC. Rinsate blank results for the 1993 Fort Devens SSI are presented in Table E13.

ABB Environmental Services, Inc.

APPENDIX E

Inorganics. Three rinsate blanks which were analyzed for PAL inorganics were identified as SBK93124, SBK93686, and SBK93721. An additional rinsate, SBK93701, was analyzed for lead only.

Forty-four of forty-seven (94%) inorganic concentrations were below CRLs. Three elements with concentrations greater than CRLs are outlined below:

ELEMENT	FREQUENCY OF DETECTION	CONCENTRATION ($\mu\text{g}/\text{L}$)
Iron	1/2	48
Manganese	1/2	3.5
Potassium	1/2	3310

The detection of potassium in the rinsate SBK93124 was reported at a concentration of almost ten times the CRL. This may represent contamination that was introduced from sampling equipment. Overall, the rinse blank data demonstrate that decontamination procedures successfully removed inorganics from sampling equipment.

VOCs. Two rinse blanks were analyzed for VOCs. These rinse blanks are SBK93686, and SBK93721. Seventy-five of seventy-nine (95%) VOC concentrations reported for the rinsates were below CRLs. Low concentrations of target VOCs detected in at least one of the rinsates include 1,1,1-trichloroethane, methylene chloride, and chloroform. The concentrations at which these compounds were detected are outlined below:

COMPOUND	FREQUENCY OF DETECTION	CONCENTRATION ($\mu\text{g}/\text{L}$)
1,1,1-Trichloroethane	1/2	2.5
Methylene Chloride	1/2	4.0
Chloroform	2/3	1.3

Methylene chloride was detected in one rinsate blank. It was also detected in three method blanks which indicates that the source of the contamination is likely the laboratory.

Chloroform contamination was observed in the rinsate blanks at roughly the same concentrations as those in the method blanks (1.1 $\mu\text{g}/\text{L}$ method blank versus 1.3 $\mu\text{g}/\text{L}$ rinsate blank). Based on method blank data, the presence of chloroform is likely due to laboratory contamination.

The detection of 1,1,1-trichloroethane in one rinsate blank represents low level contamination. The lot associated with this detection is GBOA. 1,1,1-Trichloroethane was not detected in method blanks. This compound was also detected at similar concentrations in rinse blanks collected during the 1992 field program. The maximum concentration detected for 1,1,1-trichloroethane is well below the federal drinking water standard of 200 $\mu\text{g}/\text{L}$. Based on rinsate blank data, low concentrations of 1,1,1-trichloroethane reported as sample results may be present as introduced contamination.

SVOCs. One rinsate blank was analyzed for SVOCs. The rinsates used for this analysis are SBK93686. Ninety-six of ninety-seven (99%) possible SVOC concentrations were below CRLs. The only SVOC detected was di-n-butyl phthalate at 91 $\mu\text{g}/\text{L}$. This compound was observed in laboratory method blanks and was likely introduced at the laboratory.

Explosives. One rinsate blank was analyzed for explosives. The rinsate blank used for explosives analysis were SBK93686. One hundred percent of the concentrations reported for explosive compounds were below respective CRL values.

Pesticides/PCBs. One rinsate blank was analyzed for pesticide/PCB contamination. The rinsate used for this analysis was SBK93686. One hundred percent of pesticide/PCB compounds were reported in concentrations below respective CRL values.

Nitrate/Nitrite as Nitrogen. One rinse blank was analyzed for nitrate/nitrite as nitrogen and total Kjehldahl nitrogen analyses using USAEC Methods TF22 and Method TF26. This rinse blank was SBK93686. The concentrations obtained for both analyses were below CRLs.

APPENDIX E

Phosphate/Chloride/Sulfate Ions. One rinse blank was collected for phosphate and chloride/sulfate analyses using USAEC Methods TF27 and TT10. The rinse blank was SBK93686. Concentrations were below CRLs for all three rinsates.

USEPA Methods. Standard USEPA analyses were performed to measure: alkalinity, hardness, total petroleum hydrocarbons (TPHC) and TSS.

The rinse blank SBK93686 was analyzed for concentrations of alkalinity, hardness, and TSS. Alkalinity was reported below the RL of 5,000 µg/L. The rinse blank was SBK93686. The hardness concentration was below the RL of 1,000 µg/L. The TSS concentration for this rinse blank was below the RL of 4 µg/L.

One rinse blank was analyzed for TPHC. This rinse blank was SBK93721. The concentration obtained was below the RL of 178 µg/L.

E.2.2.3 Trip Blanks

Trip blanks were shipped with all field samples which were analyzed for VOCs. Trip blanks were prepared at the contract laboratory by pouring previously analyzed deionized water into 40 mL vials. Two of these vials were sent with each shipment. The purpose of collecting trip blank data was to determine whether cross contamination by VOCs occurred during the shipment and handling of samples.

E.2.2.3.1 1992 Trip Blanks. Trip blank data for the 1992 SI are presented in Table E14. These trip blanks are DVTRP111, DVTRP112, DVTRP113, DVTRP118, DVTRP121, and DVTRP124. Two hundred twenty-three of two hundred twenty-four possible trip blank VOC results (99.5%) were concentrations below CRL. The only VOC detected in any of the trip blanks was acetone. The frequency at which this compound was detected was one of six trip blanks. The concentration at which acetone was detected was 29 µg/L. Acetone is frequently used by commercial laboratories as a solvent and for cleaning glassware. Acetone was detected at roughly the same concentration (0.027 µg/g) as that of the trip blank in the soil method blank. This provides supporting evidence that indicates that the source of the acetone is likely to be the laboratory. The trip blank data indicate that VOC cross contamination did not occur in the shipment and handling of field samples.

E.2.2.3.2 1993 Trip Blanks. Trip blanks were analyzed for VOC concentrations using Method UM20. Trip blank results for the 1993 Fort Devens SSI are presented

ABB Environmental Services, Inc.

in Table E15. Six hundred fifty three of six hundred sixty-three possible VOC results (98%) were below CRL values. The most frequently detected VOC was methylene chloride. Eight of the fifteen trip blanks (53%) had concentrations ranging from 2.6 to 17 $\mu\text{g}/\text{L}$. Method blanks were contaminated with methylene chloride at concentrations of 6.9 to 9.1 $\mu\text{g}/\text{L}$. The detections in trip blanks of methylene chloride are attributed to laboratory contamination. Chloroform and total xylenes were also detected in trip blanks at concentrations above the corresponding CRL values. Chloroform was detected in one trip blank of the fifteen at a concentration of 0.81 $\mu\text{g}/\text{L}$. Chloroform was also detected in method blanks at 0.6 to 1.3 $\mu\text{g}/\text{L}$. Trip blank concentrations of chloroform are attributed to laboratory contamination. Total xylenes were detected at 1.9 $\mu\text{g}/\text{L}$. This detection may represent cross contamination from contaminated field samples which were shipped with the trip blank DVTRP724. Samples analyzed in the same lot (ICNA) with similar concentrations should be considered estimated or suspected as possible false positives.

E.3.0 MATRIX SPIKE AND DUPLICATE QUALITY CONTROL

Matrix Spikes. Matrix spike and matrix spike duplicate samples were collected at a rate of one per twenty environmental samples (5%) during field programs conducted in 1992 and 1993. The purpose of collecting these samples was to measure the effect of the matrix on the recovery of known concentrations of target analytes. A summary of matrix spike data is presented in Table E16 (1992) and Table E17 (1993). Data have been segregated by method to show recovery trends of particular analytes. In the tables, matrix spikes have been paired with the corresponding matrix spike duplicates to make recovery comparisons. The relative percent differences (RPD) between recoveries of the matrix spikes and the matrix spike duplicates have been calculated and are listed next to the percent recovery. The average recoveries, and maximum and minimum recoveries for each method are also included as a way of measuring trends.

The criteria used for interpreting MS/MSD data are the analytical USEPA Contract Laboratory Program (CLP), Statement of Work (SOW) (USEPA, 1989) protocols and the POP for Fort Devens Volume III (USAEC, 1992). Interpretations of the MS/MSD results are contained in Subsections 3.1 and 3.2 for the 1992 and 1993 field programs.

APPENDIX E

VOC and SVOCs

For VOCs and SVOCs, matrix effect assessments were made based on surrogate recovery data rather than recoveries of the actual target analytes themselves.

Surrogate recovery data was used to evaluate matrix effects and to determine the accuracy of the VOC and SVOC methods used. Target analytes were not spiked into field samples for MS/MSD analysis. Surrogates which were spiked into VOC samples include 1,2-dichloroethane-D4, 4-bromofluorobenzene, and toluene-D8.

Recovery criteria for these surrogates, taken from the Fort Devens POP, are presented below:

SURROGATE	WATER LIMITS	SOIL LIMITS
1,2-Dichloroethane-D4	76% to 114%	70% to 121%
4-Bromofluorobenzene	86% to 115%	74% to 121%
Toluene-D8	88% to 110%	81% to 117%

The SVOC surrogates used include the following: 2-fluorophenol, phenol-D6, 2,4,6-tribromophenol, nitrobenzene-D5, 2-fluorobiphenyl, and terphenyl-D14.

Recovery criteria for these surrogates, as specified in the Fort Devens POP, are presented below:

SURROGATE	WATER LIMITS	SOIL LIMITS
2-Fluorophenol	21% to 100%	25% to 121%
Phenol-D6	10% to 94%	24% to 113%
2,4,6-Tribromophenol	10% to 123%	19% to 122%
Nitrobenzene-D5	35% to 114%	23% to 120%
2-Fluorobiphenyl	43% to 116%	30% to 115%
Terphenyl-D14	33% to 141%	18% to 137%

Duplicates. Field duplicate samples were collected every twenty samples. Duplicates are differentiated from original samples in the field sample number code. The second character of the code had a "D" in place to denote the duplicate.

The purpose of collecting duplicate samples was to measure the precision of the sampling and analytical techniques. The method by which this was measured is through the calculation of the RPD for each sample/duplicate pair. The RPD is the difference of the results divided by the average. The smaller the RPD, the more closely the results agree. The more closely the results agree, the greater the sampling and analytical precision. The RPD has been calculated for each pair of samples/duplicates. Interpretations of duplicate data are presented in Subsections 3.1 and 3.2 for the 1992, 1993, and 1994 field programs.

E.3.1 1992 MATRIX SPIKES AND FIELD DUPLICATES

Matrix Spike Results

Interpretations of the MS/MSD results for each study area in which MS/MSDs were collected are contained in this section. MS/MSD data was available for SA 41 only.

One soil sample was collected from Study Area 41 for matrix spike analysis. This sample is DX410400. DX410400 was spiked and analyzed using the following methodologies: inorganics (USAEC Methods JB01, JD15, JD17, JD19, JD24, JD25, JS16), pesticides (USAEC method LH10), PCBs (USAEC method LH16) and explosives (USAEC method LW12). Matrix spike data is presented in Table E-1b.

Inorganics. Matrix spike analysis of DX410400 included an assessment of the recoveries of the following elements: antimony, arsenic, beryllium, cadmium, chromium, copper, lead, mercury, nickel, selenium, silver, thallium, and zinc. MS/MSD criteria for recoveries are outlined in the Fort Devens POP (USAEC, 1992) and USEPA Regional data validation guidelines (USEPA, 1988).

The USEPA Regional CLP criteria for inorganic MS/MSDs is a recovery of 75% to 125%. Twenty-seven of twenty-eight (96%) matrix spike recoveries were within the CLP recovery range. The only recovery outside the CLP range was for arsenic. MS/MSD recoveries for this element were 102% and 137%. Overall, the inorganic MS/MSD data indicate that there were no significant matrix effects. The data also indicate that the methods used in the inorganics analyses provided accurate results.

ABB Environmental Services, Inc.

APPENDIX E

The RPD data from Table D16 indicate that there was good precision demonstrated for these same methods. Specifically, RPD values range from 0.2% to 29%.

Pesticides/PCBs. Pesticide and PCB compounds were also spiked into the sample DX410400 to determine matrix effects. Surrogate recoveries of decachlorobiphenyl and tetrachlorometaxylene were also used to measure matrix effects on pesticide and PCB compounds. Recovery limits as outlined in the Fort Devens POP (USAEC, 1992) of 60% to 150% were used as a guideline for evaluating target analyte and surrogate recoveries.

Nineteen of twenty (95%) matrix spike recoveries of pesticide/PCB compounds and surrogates were within recovery limits. The only recovery outside of this recovery range was for that of Aroclor 1016. The recovery of this analyte was 59%. Overall, the MS/MSD data for pesticides/PCBs indicate that there were no matrix effects for the sample DX410400 and that the methods used provided accurate results.

Explosives. Explosive compounds were spiked into the sample DX410400 for MS/MSD recovery analysis for USAEC Method LW12. The criteria used for the assessment of the recoveries of these compounds were taken from the Fort Devens Project Operations Plan, Volume III and are summarized below:

COMPOUND	WATER LIMITS	SOIL LIMITS
2,4-Dinitrotoluene	57% to 107%	62% to 112%
Nitrobenzene	61% to 111%	69% to 119%
RDX	60% to 110%	69% to 119%
1,3,5-Trinitrobenzene	60% to 110%	71% to 121%
2,4,6-Trinitrotoluene	60% to 110%	72% to 122%

There were no criteria available to assess the recoveries of PETN and nitroglycerine.

Eighteen of twenty (90%) MS/MSD recoveries of explosive compounds were within specified recovery ranges. There were no matrix effects observed for the other explosive compounds. RPD data indicate excellent precision of explosive compounds results. RPDs ranged from 0.4% to 2.9%.

1992 VOC Surrogate Recoveries. The 1992 VOC surrogate recovery data is presented in Table E 16. The surrogate recoveries for 1,2-Dichloroethane-D4 ranged from 96% to 108% for nine samples from Study Areas 41 and 43J. One hundred percent of the soil recoveries were within criteria. Recoveries for the same surrogate ranged from 102% to 112% for seven water samples from Study Area 41. One hundred percent of the water recoveries of 1,2-Dichloroethane-D4 were within criteria.

The surrogate recoveries for 4-bromofluorobenzene ranged from 88% to 124% for ten soil samples. Eight of nine (89%) of the soil recoveries were within recovery limits. The soil sample with a BFB recovery outside of the acceptable recovery range is BX43J105. 4-Bromofluorobenzene recoveries for seven water samples ranged from 88% to 90%. One hundred percent of the water recoveries are within recovery limits.

The surrogate recoveries for toluene-D8 ranged from 94% to 124% for ten soil samples. Eight of nine (89%) of the toluene-D8 surrogate recoveries were within the specified recovery range. The soil sample with a toluene-D8 recovery outside of the recovery range is DX410200. Toluene-D8 recoveries for seven water samples ranged from 84% to 92%. One hundred percent of these recoveries are within the acceptable recovery range.

VOC surrogate recovery data indicate that there were no matrix effects and that the accuracy for the GC/MS method used for VOC analysis was acceptable.

1992 SVOC Surrogate Recoveries. Recovery data was available for nine soil/sediment samples (eight from Study Area 41 and one from Study Area 43J) and eight water samples (all eight from Study Area 41). SVOC surrogate recovery data are presented in Table E16. The surrogate recoveries of 2-fluorophenol ranged from 51% to 122% for the nine soil samples. 2-fluorophenol recoveries for eight of nine (89%) soil samples were within QC limits. The recoveries for seven of eight water samples (88%) were within acceptable limits.

The surrogate recoveries of phenol-D6 ranged from 48% to 110% for soil samples. One hundred percent of these recoveries are within criteria. Water sample recoveries for phenol-D6 ranged from 80% to 150%. Seven of eight (88%) of these recoveries fall within the acceptable recovery range. The sample associated with the outlier recovery of 150% is WX4104XX.

APPENDIX E

The surrogate recoveries of 2,4,6-tribromophenol ranged from 28% to 89% for the soil samples. One hundred percent of these recoveries are within acceptable limits. Surrogate recoveries for water samples ranged from 54% to 63%. One hundred percent of these recoveries are within the acceptable limits.

The surrogate recoveries of nitrobenzene-D5 ranged from 42% to 100% for soils. One hundred percent of these recoveries are within criteria. Nitrobenzene-D5 recoveries for water samples ranged from 90% to 126%. Seven of eight (88%) of these results fall within acceptable limits. The sample associated with the outlier recovery of 126% is WX4104XX.

The surrogate recoveries for 2-fluorobiphenyl ranged from 52% to 106% for the soil samples. One hundred percent of these recoveries are within specified recovery limits from Table 3-3. 2-fluorobiphenyl recoveries for the water samples ranged from 90% to 126%. Seven of eight (88%) recoveries were within acceptable limits. The sample WX4104XX was associated with the recovery which exceeded acceptable limits.

The soil surrogate recoveries for terphenyl-D14 ranged from 58% to 109%. One hundred percent of these results are within criteria. Recoveries for the same surrogate for water samples ranged from 98% to 136%. One hundred percent of the water recoveries are within acceptable limits.

The SVOC surrogate data for soil samples indicate that there were no recovery problems for the majority of samples. The majority of surrogate recoveries were within criteria for water samples also. However, the surface water sample WX4104XX had recoveries which exceeded criteria for four of the six surrogates. Based on surrogate recovery data, SVOC concentrations for this sample may be biased slightly high.

Duplicate Results. Field duplicate samples were collected at the same rate as the MS/MSD samples. Duplicates were differentiated from samples in the identification code by inserting a "D" in the second digit. The duplicate code is identical to the conjugate sample code except for this digit.

Duplicate samples collected from SA 12, 13, 14, 27, 41, 42, and 43 during the 1992 SI. Duplicate samples were analyzed for the following classes of analytes: VOC,

APPENDIX E

SVOC (BNA), inorganics, explosives, pesticides/PCBs, TPHC, and water quality parameters. Duplicate sample data are presented in Table E16.

Duplicates of field samples were collected to measure the precision of the results. They were collected at a rate of five percent per matrix for the following parameters: inorganics, VOCs, BNAs, explosives, PCBs, TOC and TPHC.

One soil sample and a duplicate, DX120200 and DD120200, were used for the above analyses.

Inorganics. The following elements with their respective methods are included in the inorganic analyses: Se (USAEC Method JD15), Pb (USAEC Method JD17), As (USAEC Method JD19), Ti (USAEC Method JD24), Sb (USAEC Method JD25) and Ag, Al, Ba, Be, Ca, Cd, Co, Cu, Cr, Fe, K, Mg, Mn, Na, Ni, V, Zn (USAEC Method JS16).

Concentrations of the following elements were found above the respective CRL: Pb, As, Al, Ba, Ca, Co, Cr, Cu, Fe, K, Mg, Mn, Na, Ni, V and Zn. There was generally good agreement of the sample results with the duplicate results. The RPDs for these elements ranged from 0.7% to 36.3%. Only one RPD exceeded the EPA Region I limit of 30%. This difference was seen in the ICAP analysis for calcium. All other differences were below the 30% EPA threshold.

The inorganics results show good precision. They demonstrate the laboratories ability to exhibit reproducibility of the results.

VOCS. The concentrations of volatile organic compounds were measured for DX120200 and DD120200. There was good agreement in the concentrations of these compounds because none of them were detected above CRL except acetone. Acetone was detected in both of the samples. The RPD of the results was 96.3%. Acetone possibly was introduced as a laboratory contaminant. However, acetone is not found in any Group 2 and 7 SI method blanks. Trip blanks, field flanks, and rinsate blanks also did not have concentrations above CRL. Refer to Section 2 for a discussion of these parameters. Three of the four pairs of Group 2 and 7 soil samples/duplicates had concentrations of acetone above the CRL of 0.017 $\mu\text{g/g}$. The RPDs show lack of consistency for acetone results.

ABB Environmental Services, Inc.

APPENDIX E

BNA. BNA concentrations were measured for the SA 12 sample/duplicate pair. The samples were also tested for PCB contamination using the same BNA method. All of the BNA and PCB concentrations were below CRL values. This shows good agreement for these nondetect results.

Explosives. Explosive compounds were not detected above CRL in the SA 12 sample and duplicate. The results were consistent in showing a lack of contamination with these compounds.

Other Methods. Other non-certified methods were used in the analysis of DX120200 and DD120200. These methods were used to measure for PCBs, TOC and TPHC.

PCB analysis, using ESE Laboratory techniques, detected no PCBs above CRL. The nondetect results in both the sample and duplicate show good agreement.

The TOC results for the sample and duplicate have an RPD of 1.3%. An RPD of this amount shows good precision of the results.

In TPHC analyses of the sample and duplicate low level petroleum contamination was reported in both samples. There is an RPD of 2.4% between the results. Since the RPD is so low good precision is demonstrated in the execution of the method analysis for this lot.

Field duplicates were collected at SA 13 to measure the precision of sampling and analysis results.

Inorganics. The inorganic analysis of the SA 13 duplicates included the following elements using the respective methods: Hg (USAEC Method SB01), Tl (USAEC Method SD09), Pb (USAEC Method SD20), Se (USAEC Method SD21), As (USAEC Method SD22), Sb (USAEC Method SD28), and Ag, Al, Ba, Be, Ca, Cd, Co, Cr, Cu, Fe, K, Mg, Mn, Na, Ni, V, Zn (USAEC Method SS10).

Tl, Se, Sb, Ag, Be, Ca, Cd, Co, Cr, and Ni were not detected above the CRL in either WX130200 or WD130200. The sample results were in complete agreement with the duplicate results. For these elements there is good precision demonstrated by the laboratories. Some of the elements are analyzed using Method SS10. There is a high RPD for some of the results for elements included in this method. Elements analyzed by Method SS10 for which the RPD exceeded the EPA Region I

ABB Environmental Services, Inc.

APPENDIX E

limit include Cu (64%) and Zn (40.5%). The elements Al, Ba, Ca, Fe, K, Mg, Mn, Na, and V were detected using the same method. However, the RPD for these methods was below the 30% EPA limit.

Lead and arsenic, for which alternate aqueous inorganic methods are used, were also present in WX130200 and WD130200. The RPD between the results was 64.8% for Pb and 40.8% for As. These RPDs exceed the EPA Region I advisory limit of 30%. This should be taken into consideration when Pb and As sample results from SA 13 are reviewed.

BNAs. AEC Method UM18 was used to analyze BNA compounds in water for SA 13 duplicate analysis. PCB compounds were also included in the UM18 analysis. None of the BNA nor the PCB compounds were detected above the CRL values. There was complete agreement between the sample and duplicate results. There was good precision demonstrated in the execution of this method.

VOCs. AEC Method UM20 was used for VOC duplicate analysis. No VOCs were detected above CRL in the water sample and its duplicate, WX130200 and WD130200. There was good precision demonstrated for these nondetect samples.

Explosives. AEC Method UM32 was used to determine explosive compounds concentrations in WX130200 and WD130200. In addition, AEC Method UW19 was used to determine concentrations of the explosives nitroglycerine and PETN. Concentrations of explosive compounds for both methods were below the corresponding CRLs. There was complete agreement between sample results and duplicate results.

Other Methods. Duplicate analysis was also performed for the following methodologies: total Kjeldahl nitrogen, nitrate/nitrite as nitrogen, phosphate, chloride/sulfate ion, alkalinity, hardness, TPHC and TSS.

USAEC Method TF26 was used to measure total Kjeldahl nitrogen levels in WX1302XX and WD1302XX. Nitrogen was found in both samples at 4,380 $\mu\text{g}/\text{L}$ and 3,240 $\mu\text{g}/\text{L}$, respectively. There was an RPD of 29.9% between these values. This represents good precision for this method.

USAEC Method TF22 was used to measure nitrate/nitrite as nitrogen values for a water sample and its duplicate. Concentrations of nitrogen were reported at

ABB Environmental Services, Inc.

APPENDIX E

26.3 $\mu\text{g}/\text{L}$ and 11.3 $\mu\text{g}/\text{L}$. An RPD of 79.8% was calculated for these values. A difference of this magnitude indicates poor agreement between the concentrations.

Phosphate concentrations were measured using USAEC Method TF27. Values of 406 $\mu\text{g}/\text{L}$ and 475 $\mu\text{g}/\text{L}$ were reported for the water sample and duplicate. This represents a 15.7% RPD between the two. The results show good precision for the method.

USAEC Method TT10 was used to determine chloride/sulfate ion concentration in WX130200 and WD130200. Chloride ion levels were the same for both samples at 40,000 $\mu\text{g}/\text{L}$. Sulfate ion concentrations were 63,700 $\mu\text{g}/\text{L}$ and 64,300 $\mu\text{g}/\text{L}$. The RPD for sulfate results is 0.9%. There is good precision for the method in the analysis of both ions.

WX130200 and WD130200 were used in assessing the precision of the alkalinity method for SA 13. An RPD of 0.9% was calculated for the results. This indicates good agreement for the method.

Hardness results were 179,000 $\mu\text{g}/\text{L}$ and 172,000 $\mu\text{g}/\text{L}$ for WX130200 and WD130200, respectively. AN RPD of 4% was calculated as the difference between these values. Good precision is demonstrated for this method.

TPHC results for the water sample and duplicate were both below the CRL of 200 $\mu\text{g}/\text{L}$. Since the RPD is 0% there is excellent precision shown in the analysis.

TSS results for WX130200 and WD130200 are 80,000 $\mu\text{g}/\text{L}$ and 160,000 $\mu\text{g}/\text{L}$. The RPD for these results is 66.7%. This represents a significant variance in concentrations. The variance is most likely due to a lack of homogeneity of suspended solids in the samples. The variability of the results should be considered during review of TSS results.

Field duplicates were collected to measure the precision of the sampling and analysis results. One soil sample and duplicate from SA 14, DX140200 and DD140200, were used for the analyses.

Inorganics. The following elements are included in the inorganics duplicate review: As (USAEC Method JD19), Se (USAEC Method JD15), Pb (USAEC Method JD17), Tl 6 (USAEC Method JD24), Sb (USAEC Method JD25) and Ag,

ABB Environmental Services, Inc.

APPENDIX E

Al, Ba, Be, Ca, Cd, Co, Cr, Cu, Fe, K, Mg, Mn, Na, Ni, V, Zn (USAEC Method JS16).

Every element except for Tl, Sb and Ag was detected above CRL in at least one of the duplicate pair of samples. There was agreement in the sample and duplicate results for the non-detect Tl, Sb and Ag results. Se was detected above CRL in one sample but was below this value in the duplicate. The Se concentrations measured in the recoveries were $<0.250 \mu\text{g/g}$ and $1.12 \mu\text{g/g}$. Although these results are inconsistent, the values being compared are small enough that even small differences result in high RPDs. The RPD in the present case is 127%. Allowances are made for this in the EPA Region I SOW.

Cd results for DX140200 and DD140200 are $8.29 \mu\text{g/g}$ and $30.3 \mu\text{g/g}$. A 114% RPD was calculated for the difference of these results. K results were $450 \mu\text{g/g}$ and $750 \mu\text{g/g}$. The RPD for these results is 50%. These RPDs do not meet the EPA CLP requirement for inorganic soil of $<50\%$ RPD. The inconsistency of the results is most likely due to a lack of homogeneity in the sample. This should be taken into consideration during the review of the data.

BNAs. USAEC method LM18 was used for BNA duplicate analysis. Pesticide and PCB compounds were included in the analysis. No BNA, pesticide or PCB compounds were detected above CRL in either DX140200 or DD140200.

VOCs. USAEC method LM19 was used for VOC duplicate analysis. VOCs were reported in concentrations below CRL except for acetone and xylene. Acetone results for DX140200 and DD140200 were $0.160 \mu\text{g/g}$ and $1.000 \mu\text{g/g}$. There is an RPD of 144.8% for these results. The presence of acetone in these samples is most likely due to introduction at the laboratory.

Xylene was measured at $0.023 \mu\text{g/g}$ in DD140200 and at $<0.008 \mu\text{g/g}$ in DX140200. There is a 96.8% RPD for these values.

Explosives. USAEC method LW12 was used for explosives duplicate analysis. Explosive compound concentrations were not detected above CRL in either DX140200 or DD140200 except for 2,4-Dinitrotoluene and nitroglycerine. 2,4-Dinitrotoluene was reported at $0.894 \mu\text{g/g}$ in DX140200 and at $<0.424 \mu\text{g/g}$ in DD140200. The RPD for these values is 71.3%. The variability of these results can

ABB Environmental Services, Inc.

APPENDIX E

be due to lack of homogeneity of the soil sample. This needs to be taken into consideration when reviewing sample concentrations of this compound.

Nitroglycerine concentrations in the two samples was measured at 22.3 $\mu\text{g/g}$ and 26 $\mu\text{g/g}$. An RPD of 15.3% demonstrates good precision for the method.

Other Methods. Other methods for which duplicate analyses were performed are TPHC and pesticides. The methods that were used are not AEC certified. Petroleum contamination was observed in both soil samples. TPHC results were reported at 248 $\mu\text{g/g}$ and 231 $\mu\text{g/g}$ for DX140200 and DD140200, respectively. The RPD of the two concentrations is 7.1%. The laboratory demonstrated reproducibility of the results for the method.

The pesticide compounds alpha-chlordan, gamma-chlordan and heptachlor were tested for using ESE Laboratories techniques. None of these compounds were detected above the CRL in either DX140200 or DD140200.

One SA 41 water sample with a duplicate, WX4102XX and WD4102XX, was analyzed using the following methodologies: inorganics (USAEC method SB01, SD09, SD20, SD21, SD22, SD28, and SS10), BNAs (USAEC method UM18), VOCs (USAEC method UM20), explosives (USAEC method UW32), alkalinity, hardness, TPHC and TSS.

Inorganics. WX4102XX and WD4102XX were analyzed using the respective methods for the following elements: Hg (USAEC method SB01), Tl (USAEC method SD09), Pb (USAEC method SD20), Se (USAEC method SD21), As (USAEC method SD22), Sb (USAEC method SD28), Ag, Al, Ba, Be, Ca, Cd, Co, Cr, Cu, Fe, K, Mg, Mn, Na, Ni, V and Zn (USAEC method SS10). The following elements were detected in concentrations above their respective CRLs: Pb, As, Al, Ba, Be, Ca, Fe, K, Mg, Mn, and Na. CLP criteria for the RPD between sample and duplicate results were used to assess the precision. The CLP criteria is for the RPD to be no greater than 30% between results. The RPD was greater than 30% for the following elements: Pb (144%), As (47%), Al (127%), Ba (72%), Fe (67%), K (89%) and Mn (65%). The variance of results for these elements could be due to a lack of homogeneity in the sample. In general, there is good consistency shown for the inorganic methods.

APPENDIX E

BNAs. USAEC method UM18 was used to measure BNA concentrations in WX4102XX and its duplicate. None of the target BNA compounds were detected above CRL in either of these samples. The results were consistent in these determinations.

VOCs. USAEC method UM20 was used to measure VOC concentrations in the water sample and its duplicate. No VOCs were reported above CRL for either of the two samples.

Explosives. USAEC method UW32 was used to measure the concentrations of explosive compounds in WX4102XX and WD4102XX. None of these compounds were found above their corresponding CRLs in either of the two samples.

Other Methods. Duplicate analysis was also performed to measure precision for other methods including alkalinity, hardness, TPHC, and TSS.

Alkalinity results for WX4102XX and WD4102XX were both 11,000 $\mu\text{g}/\text{L}$. The RPD was 0% between the results showing excellent precision for the method.

The results for hardness for the sample and duplicate were 26000 $\mu\text{g}/\text{L}$ and 16,600 $\mu\text{g}/\text{L}$. The RPD for these results was calculated to be 44%. This represents a significant difference between the two results.

The results for TPHC analysis done for WX4102XX and WD4102XX were both below the CRL of 200 $\mu\text{g}/\text{L}$ for this method. The results are consistent for this method.

The TSS results for the sample and duplicate water samples are 30,000 $\mu\text{g}/\text{L}$ and 32,000 $\mu\text{g}/\text{L}$. The RPD of these results is 6.5%. An RPD of this amount indicates good consistency in the execution of this method.

Inorganics. One SA 42 water sample with a duplicate was collected for inorganic testing. These samples are WX4203XX and WD4203XX. The following elements with their respective methods were included in the analyses: Hg (USAEC Method SB01), Tl (USAEC Method SD09), Pb (USAEC Method SD20), Se (USAEC Method SD21), As (USAEC Method SD22), Sb (USAEC Method SD28) and Ag, Al, Ba, Be, Ca, Cd, Co, Cr, Cu, Fe, K, Mg, Mn, Na, Ni, V, Zn (USAEC Method SS10).

ABB Environmental Services, Inc.

APPENDIX E

Table E16 lists the relative percent difference (RPD) between the sample and field duplicate. The range of RPDs for inorganics is from 0% to 45%. The EPA Region I requirement for water samples is an RPD of no greater than 30%. The RPDs for all elements meet this requirement with the exception of barium. The RPD for barium was 45%. For sixteen of the elements there was an RPD of 0%.

The inorganics duplicate results indicate good precision. This is an indication that the laboratory has been consistent in the analysis for these elements.

VOCs. One water sample and duplicate were submitted for VOC analysis. These samples are WX4203XX and WD4203XX. USAEC Method UM20 was used to determine concentration of VOC compounds in these samples. The RPD was calculated to measure how closely these results agree.

Of the thirty-nine compounds included in the UM20 method only one toluene, was detected above the CRL. The RPD between the sample and duplicate was 10.5%. This is well below the EPA Region I limit of 30%.

All other compounds were not detected above respective CRLs for WX4203XX and WD4203XX. The RPD for these results is 0.

There is good agreement between the sample and duplicate results.

BNAAs. One water sample and duplicate was collected for BNA analysis under USAEC Method UM18. These samples are WX4203XX and WD4203XX. Pesticides and PCBs compounds were also included in the UM18 method.

None of the BNA compounds were found in the WX4203XX. None were found in WD4203XX. This indicates good agreement in the results. It also indicates consistency of the BNA analysis by the laboratory.

Explosives. USAEC Method UW32 and UW19 was used to test one SA 42 water sample and duplicate. These samples are WX4203XX and WD4203XX.

None of the explosive compounds were detected in either sample. The RPD for these compounds was therefore 0%. This indicates good precision in the results.

APPENDIX E

Other Methods. Duplicate analysis for SA 42 samples was performed for nitrate/nitrite as nitrogen, total Kjeldahl nitrogen, total phosphates, chloride/sulfate ion, TSS, hardness and alkalinity. One water sample plus a duplicate was collected for all of these methods. These are WX4203XX and WD4203XX.

USAEC Method TF22 was used to test the samples for nitrate/nitrite as nitrogen. Both the sample and duplicate were found to be below the CRL of 10 $\mu\text{g}/\text{L}$. This indicates agreement and good precision of the results for this method.

USAEC Method TF26 was used for total Kjeldahl nitrogen analysis of WX4203XX and WD4203XX. From Table E12 it can be seen that there is a 21.8% RPD between the samples. This is below the EPA Region I criteria for water samples of 30%.

USAEC Method TF27 was used for phosphate concentration determination. Both samples had detectable levels of phosphate. The concentration of phosphate in WX4203XX is 228 $\mu\text{g}/\text{L}$ and 178 $\mu\text{g}/\text{L}$ in WD4203XX. The RPD between these results is 24.6%. This is below the EPA Region I criteria for water samples of 30%.

USAEC Method TT10 was used to determine the concentrations of the chloride and sulfate ions. Neither ion was detected above the respective CRL values in either the sample or the duplicate. Since there was 0 percent RPD for both ions there was good agreement and precision demonstrated for this method.

Other methodologies for which there are no corresponding USAEC methods were used at SA 42. These include TSS, hardness and alkalinity. A water sample and duplicate, WX4203XX and WD4203XX, were used for these tests.

The TSS analysis results were 175,000 $\mu\text{g}/\text{L}$ and 136,000 $\mu\text{g}/\text{L}$. The RPD between these results is 25%.

Hardness results were 17,800 $\mu\text{g}/\text{L}$ and 8,800 $\mu\text{g}/\text{L}$. The RPD of these results is 67.7%. This RPD is relatively high and should be taken into consideration during the review of SA 42 sample results for alkalinity.

Alkalinity values are 8,000 $\mu\text{g}/\text{L}$ and 9,000 $\mu\text{g}/\text{L}$. The RPD of these results is 11.8%. A difference of this magnitude reflects good precision for the method.

ABB Environmental Services, Inc.

APPENDIX E

Two soil sample/duplicate pairs from SA 43 sites 43O and 43H were analyzed using the following methodologies: inorganics (Pb only) in soil (AEC method JD17), VOCs in soil (AEC method LM19), and TPHC. The two soil samples were identified as BX43O105/BD43O105 and BX43H109/BD43H109. EPA CLP criteria, where available, was used to assess the RPDs of the various methods.

Inorganics. USAEC method JD17 was used to assess the precision of lead in soil results for the two duplicate pairs collected from SA 43. The EPA CLP criteria for inorganics calls for a RPD value of no more than 50% for soil samples. There was an RPD value of 7.6 % calculated for the BX43O105 pair and an RPD value of 45% calculated for the BX43H109 pair. These values meet CLP protocols. There was good precision shown for in the analysis of lead for these samples.

VOCs. USAEC method LM19 was used to obtain results to measure the precision of VOC concentrations. There were no VOC concentrations above CRL reported for the method with the exception of acetone. Acetone was detected in one sample of the duplicate pair of BX43O105 at 0.032 $\mu\text{g/g}$. An RPD of 61% was reported. As noted in Section 2 of this appendix, acetone is classified by the EPA as a common laboratory contaminant. This is the likely source of this compound in this particular sample. Overall there is excellent consistency of the VOC nondetect results.

TPHC. The sample pairs BX43O105/BD43O105 and BX43H109/BD43H109 were also analyzed for TPHC concentrations. These concentrations were evaluated to determine the precision of these results. The results of the duplicate pair BX43O105/BD43O105 were both below the CRL. The results of the sample pair BX43H109/BD43H109 were not as consistent with one sample reported at below CRL and the other at 154 $\mu\text{g/g}$. The RPD of these results is 139%. The precision shown for this method is mixed, given the results for the pairs of duplicates.

One duplicate water sample, MX2702X1, was collected from SA 27. Duplicate results are presented in Table E16 in this appendix. The sample pair were analyzed using the following methodologies: inorganics (USAEC methods SB01, SD09, SD20, SD21, SD22, SD28, SS10), VOCs (USAEC method UM20), BNAs (USAEC method UM18), explosives (USAEC method UW19 and UW32), nitrate/nitrite as nitrogen (AEC method TF22), alkalinity, chloride/sulfate ions, and TPHC.

APPENDIX E

EPA Region 1 guidelines were used to assess the RPDs of inorganics, BNAs, and VOCs. These guidelines provide criteria as to whether there is good precision of the results.

Inorganics. The following elements were included in the inorganics duplicate review for the SA 27 water sample MX2702X1: Ag, Al, As, Ba, Be, Ca, Cd, Co, Cr, Cu, Fe, Hg, K, Mg, Mn, Na, Ni, Sb, Se, Tl, V, and Zn.

The EPA Region I criteria for the RPD of inorganic methods is 50% for soils and 30% for waters. The RPD of the reported results for all of the elements were within the 30% limit. The range of RPDs for all elements was from 0% to 23%. The biggest difference in concentrations was found in chromium results. The low RPD values demonstrate consistency by the laboratory for all inorganic methods.

VOCs. USAEC method UM20 was used to determine the precision of measuring VOC concentrations in duplicates of the water sample MX2702X1. No VOCs were reported above CRL in either of the duplicate pair.

BNAs. USAEC method UM18 was used to measure the precision of the BNA results in the duplicate water sample pair of MX2702X1. There were no BNA compounds detected in either sample of the duplicate pair.

Explosives. USAEC methods UM19 and UW32 were used to measure the precision of the reported concentrations of explosive compounds. The water samples MX2702X1 and its duplicate were used to provide this information. None of the compounds were detected above CRL in either sample. There was good agreement of these nondetect results.

Other Methods. An evaluation was also performed on the results of the nitrate/nitrite as nitrogen, chloride/sulfate ion, TPHC and alkalinity analyses. The water sample MX2702X1 was used for all methods.

USAEC method TF22 was used to measure the concentration of nitrate/nitrite as nitrogen in the duplicate sample pair. Values of 187 $\mu\text{g}/\text{L}$ and 840 $\mu\text{g}/\text{L}$ were obtained from the analysis. The RPD of these results was calculated to be 127%. The lack of agreement for these results show poor precision by the laboratory in performing this particular method.

ABB Environmental Services, Inc.

APPENDIX E

USAEC method TT10 was used to measure chloride and sulfate ion concentrations in the duplicate sample pair of MX2702X1. There was good agreement of the results for both ions because neither one was detected above their respective CRLs in either sample. The CRL of chloride ion is 2,120 µg/L while that of the sulfate ion is 10,000 µg/L.

TPHC analysis was also performed on the duplicate sample pair of the water sample. Neither sample had TPHC concentrations above the CRL. The CRL was different for the two samples because apparently there was a 1:5 dilution performed on one of them.

Alkalinity results of the duplicate water samples varied by the RPD of 22%. Concentrations were reported at 24,000 µg/L and 30,000 µg/L. These results indicate good precision of the results.

E.3.2 1993 MATRIX SPIKES AND FIELD DUPLICATES

MS/MSD samples analyzed from the Group 2 and 7 Study Areas include groundwater, surface water, and subsurface soil samples. Analyses were completed on these samples for the following chemical classes of analytes: inorganics, pesticides/PCBs and explosives. Matrix spike analyses were also completed for alkalinity, hardness, TOC, and TPHC.

Inorganics. Inorganic matrix spikes included PAL elements: USEPA CLP guidelines were used to assess MS/MSD recoveries. These guidelines specify an acceptable recovery range for inorganic elements of 75 to 125%.

Five water samples were used to collect MS/MSD data. These samples include MX4104X1, MXAF05X1, MXAF07X1, WX122700 and WX4110XX. For groundwater samples MX4104X1, MXAF05X1, and MXAF07X1, there are filtered and unfiltered inorganic MS/MSD results. The associated tables list results for unfiltered samples first, followed by results for filtered samples. Computer generated RPD results presented in the Table E17, "MS/MSD Quality Control Report", are incorrect for sample MXAF05X1. The computer calculated RPD results on the table are based on filtered versus unfiltered samples, instead of filtered versus filtered and unfiltered versus unfiltered samples. Results have been manually corrected.

APPENDIX E

The aqueous inorganic matrix spike recoveries of two hundred seventy-one of three hundred ten possible results (87%) were within USEPA CLP limits. The recoveries of elements which were not within USEPA limits were associated with the samples MXAF07X1, MXAF05X1 and MX4104X1.

For the sample MXAF07X1, MS/MSD recoveries for aluminum, antimony, iron and selenium were below the lower recovery limit of 75%. According to "Region I Laboratory Data Validation Functional Guidelines For Evaluating Inorganics Analyses, February 1989" spike recoveries do not apply when sample concentration exceeds the spike concentration by a factor of 4 or more. Concentrations of aluminum and iron were greater than 4 times the spike concentration in the original sample and MS/MSD recoveries of aluminum and iron were not considered estimated due to this fact. Sample concentrations for the unfiltered water sample of MXAF07X1 are potentially biased low for antimony and selenium because of matrix effects.

For the sample MXAF05X1, MS/MSD recoveries were below the USEPA recovery limits of 75% for the following elements: aluminum, arsenic, barium, chromium, copper, iron, lead, magnesium, manganese, potassium, nickel, selenium, thallium, and zinc. Sodium was the only analyte above the USEPA recovery limit of 125% for sample MXAF05X1. Again due to the low sample spike concentration in relation to the concentration already present in the sample, spike recovery criteria does not apply for the following elements: aluminum, iron, magnesium, manganese, and potassium. Based on MS/MSD data, sample concentrations for the water sample MXAF05X1 may be biased low for arsenic, chromium, copper, lead, nickel, thallium, and zinc due to matrix effects.

For sample MX4104X1 the only analyte which was outside of USEPA Region I Recovery criteria was the iron with a recovery of 125% .

There were no matrix effects observed for the samples WX122700 and WX4110XX.

Five soil samples were spiked with target elements for MS/MSD analysis. These samples are BX410204, BXXG0512, BXXD0310, DX420500 and BXXJ0205. One hundred seventy-two of two hundred twenty-four (77%) possible inorganic soil MS/MSD recoveries were within USEPA CLP recovery limits for inorganics. Elements for which at least one MS/MSD recovery was outside USEPA limits include aluminum, antimony, arsenic, barium, iron, lead, magnesium, manganese,

ABB Environmental Services, Inc.

APPENDIX E

potassium, selenium, thallium, vanadium, and zinc. MS/MSD recoveries for some of the above elements showed a large variability for some elements including high and low results. The elements aluminum and iron showed low spike concentration in relation to the sample concentration already present in the sample so spike recovery criteria does not apply. MS/MSD soil data for the remaining elements for which MS/MSD recoveries were outside USEPA limits are summarized below:

ELEMENT	FREQUENCY OUTSIDE USEPA LIMITS*	PERCENT RECOVERY RANGE	RPD RANGE OF MS/MSDs
Antimony	1/10	64 to 103	3.5 to 11
Arsenic	8/10	112 to 827	7.3 to 107
Barium	3/10	6.1 to 104	1.0 to 163
Lead	6/10	6 to 277	4.3 to 147
Magnesium	2/10	50 to 105	0.9 to 52
Manganese	6/10	3.9 to 721	3.0 to 180
Potassium	2/10	42 to 104	1.0 to 51
Selenium	8/10	31 to 91	2.0 to 18
Vanadium	1/10	64 to 106	0.4 to 22
Zinc	1/10	73 to 110	1.6 to 24

* Counted as outside USEPA limits if either the MS or MSD recovery was an outlier.

For the elements antimony, vanadium and zinc, one of ten MS/MSD recoveries was just below the USEPA CLP limit of 75%. No serious matrix effects were attributed to the recovery of these elements. For selenium MS/MSD data show consistent low recoveries which are probably due to matrix effects. Sample concentrations of selenium are potentially biased low due to these effects. Arsenic MS/MSD results showed consistent high recoveries which are probably due to matrix effects. Sample concentration of arsenic are potentially biased high due to these effects.

Recoveries for barium, lead, and manganese were less than the USEPA Region I rejection threshold of 30% in at least one spike sample.

ABB Environmental Services, Inc.

Pesticides/PCBs. Two soil sample and one water sample were used to determine matrix effects for pesticides and PCBs. Criteria outlined in the POP (ABB-ES, 1992a) were used to assess recovery values. The criterion for pesticide/PCB compounds is a recovery range of 60% to 150%. Spiked target analytes and surrogates were evaluated.

The water sample used for MS/MSD analysis was WX122700. Twenty-eight of thirty-three (85%) possible MS/MSD recoveries were within the recovery range. At least one recovery for the surrogates decachlorobiphenyl and tetrachlorometaxylenne were outside of criteria. Recoveries of all target pesticide/PCB compounds were within the USEPA surrogate advisory limits. For this reason, it was concluded that there were no matrix effects demonstrated for the water sample used in the MS/MSD analysis.

The soil samples used for the MS/MSD analysis of pesticide/PCB compounds were BX410204 and DX420500. Sixty-one of seventy-two (85%) pesticide/PCB recoveries were within the USEPA recovery limits. Six compounds were below the USEPA surrogate advisory limits for DX420500, these were all associated with USAEC Method LH10 for pesticides analysis. Five compounds were below the USEPA surrogate advisory limits for BX410204, these were all associated with USAEC Method LH 16 for PCB analysis. All recoveries outside of USEPA surrogate recovery criteria were very close to recovery criteria except Aroclor 1016 for DX420500 which had a recovery of 36%. In general, the MS/MSD data indicate accurate measurements were obtained for pesticide/PCB compounds.

Explosives. Two soil sample and two water samples were used for MS/MSD analysis of explosive compounds. Spike compounds and criteria used for the assessment of the recoveries of these compounds were previously listed in Subsection E.3.1.

The water samples used for the MS/MSD analysis of explosives were WX122700 and WX4110XX. Twenty of twenty-six (77%) possible results were recoveries within the specified recovery ranges. All recoveries outside control limits were associated with the sample WX4110XX. The recovery associated with one sample of this MS/MSD pair was consistently outside the limits. The RPDs of the MS/MSD results for WX4110XX were also high, ranging from 68 to 118%.

The soil samples BX410204 and DX420500 were also spiked with the explosive compounds. A total of twenty-eight recoveries were obtained and one hundred

ABB Environmental Services, Inc.

APPENDIX E

percent of them were within the specified recovery range. This indicates that there were no matrix effects for the soil sample used for the MS/MSD analysis.

VOC and SVOC

1993 VOC Surrogate Recovery. VOC surrogate recovery data for samples collected during the 1993 Fort Devens SSI are presented in Table E18. Recovery criteria for surrogate recoveries were specified in the POP, Volume III and are summarized in Subsection L.3.0.

Recoveries of 1,2-dichloroethane-D8 for water samples ranged from 102 to 134%. The average recovery of this surrogate was 112%. Eighty-one of one hundred thirty-five (60%) possible recoveries were outside of the limits specified for 1,2-dichloroethane-D4. Outlier recoveries were all greater than the upper limit of the acceptable range for this surrogate suggesting that there is a slightly high bias of VOC concentrations for the water samples.

Recoveries of 1,2-dichloroethane-D8 for soil samples ranged from 80 to 112%. One hundred percent of these results were within the specified range for soil recoveries of this surrogate.

Recoveries of 4-bromofluorobenzene for water samples ranged from 72 to 102% with an average recovery of 90%. One hundred thirty-nine of one hundred fifty-seven (89%) results were within recovery limits. All outlier recoveries were below the lower limit of the specified recovery range.

Soil sample recoveries of 4-bromofluorobenzene ranged from 94 to 134% with an average of 109%. Sixty of sixty-two (97%) recoveries were within acceptable limits.

Water sample recoveries of toluene-D8 ranged from 78 to 102%. One hundred forty-nine of one hundred fifty seven (95%) recoveries were within limits specified in Table 3-5.

Toluene-D8 recoveries for soil samples ranged from 88 to 130% with an average of 106%. Fifty-six of sixty-two (90%) recoveries were within acceptable limits.

Overall, VOC surrogate data indicate that the majority of recoveries were within acceptable recovery ranges. No clear bias was observed as a general trend for all

ABB Environmental Services, Inc.

APPENDIX E

surrogates. This indicates that matrix effects were minimal and that the VOC method produced accurate results for soil and aqueous samples.

1993 SVOC Surrogate Recovery. SVOC surrogate recoveries for the Fort Devens SSI are presented in Table E18. Recovery criteria for surrogate recoveries were specified in Subsection E.3.0.

Surrogate recoveries of water samples for 2-fluorophenol ranged from 17 to 130%. Eighty-seven of one hundred nineteen (73%) of these recoveries were within the specified recovery range. Outlier recoveries were both above and below this range.

Soil sample recoveries for 2-fluorophenol ranged from 28 to 149%. Forty of fifty-nine (68%) of these recoveries were within acceptable limits.

Water sample recoveries of phenol-D6 ranged from 36 to 150% with an average of 66%. One hundred eight of one hundred nineteen (91%) recoveries were within specified limits.

For soil, forty-five of fifty-nine (76%) surrogate recoveries of phenol-D6 fell within acceptable recovery limits.

For the surrogate 2,4,6-tribromophenol, one hundred percent of the recoveries from water samples were within the specified recovery range. One hundred percent of soil recoveries of this surrogate were also within acceptable limits.

Recoveries of nitrobenzene-D5 ranged from 22 to 130% for water samples. One hundred eleven of one hundred nineteen (93%) recoveries from water samples were within the specified range. Soil sample recoveries of nitrobenzene-D5 ranged from 22 to 130%. Fifty-three of fifty-nine (90%) surrogate recoveries were within acceptable limits.

For the surrogate 2-fluorobiphenyl one hundred percent of the recoveries from water samples were within water recovery limits. Fifty-seven of fifty-nine (97%) recoveries for soil samples were within soil recovery limits.

Recoveries of the surrogate terphenyl-D14 were within respective limits for one hundred percent of water and soil samples.

ABB Environmental Services, Inc.

APPENDIX E

The SVOC surrogate data indicate that, in general, there were no matrix problems associated with SVOC samples collected during the 1993 Fort Devens SSI.

Duplicates. Duplicate sample data for the Group 2 and 7 Study Areas were collected during the 1993 Fort Devens SSI (including subsequent rounds of groundwater sampling) are presented in the Table E17. Duplicate precision was measured for inorganics, VOCs, SVOCs, and explosives. Duplicate precision was also measured for data obtained from analyses of nitrite/nitrate as nitrogen, chloride/sulfide ion, TOC, TPHC, TSS, alkalinity and bicarbonate ion. It is important to note RPD calculations based on two samples with non-detect results have been calculated and presented on the table. These RPDs are not discussed in this evaluation. The second error occurred with inorganic aqueous RPD results for MX4103X1. The computer generated RPD values based on filtered versus non-filtered concentrations, instead of filtered versus filtered and unfiltered versus unfiltered concentrations due to errors in the field sample number. Correct RPDs have been included.

Inorganics. USEPA Region I guidelines were used to assess the RPDs of the inorganic data. These guidelines specify RPD goals of less than 30% for inorganic water concentrations and 50% for inorganic soil concentrations.

The dissolved and total concentrations for four groundwater samples and total concentrations for two surface water samples were compared with those for their respective duplicates. The water samples used were MX1302X1, MX4603X1, MXG308X2, MXXJ01X1, WX121800, and WX420700. The RPDs of 200 of 224 (89%) possible duplicate results were below 30%. Elements for which USEPA Region I precision goals were not met are presented below:

ELEMENT	FREQUENCY RPD EXCEEDS 30%	RPD RANGE
Antimony	1/6	0 to 44%
Aluminum	2/10	0 to 57%
Arsenic	2/10	0 to 68%
Barium	1/10	0 to 36%
Copper	1/10	0 to 51%
Chromium	1/10	0 to 43%

ABB Environmental Services, Inc.

APPENDIX E

ELEMENT	FREQUENCY RPD EXCEEDS 30%	RPD RANGE
Copper	1/10	0 to 51%
Iron	4/10	0 to 100%
Lead	4/10	0 to 156%
Manganese	2/10	0 to 109%
Nickel	1/10	0 to 31%
Potassium	1/10	0 to 66%
Vanadium	1/10	0 to 42%
Zinc	2/10	0 to 89%

The outlier RPDs for the majority of the results are just barely above the USEPA Region I limit of 30%. Overall, the duplicate data indicate that there was good precision of the inorganic water results.

The concentrations of six duplicate pairs of soil samples were also assessed for precision. These duplicate samples are BX410230, BXXJ0210, BXXH0512, BXXH1025, DX420900 and DX410800. The RPDs of one hundred thirty-two of one hundred forty concentrations (94%) were below the USEPA Region I limit of 50%. The majority of RPD values that exceeded USEPA Region I criteria were calculated from values that were near or at the detection limits of the associated analyte, we would expect the analysis to be less precise in this area. The low frequency of RPDs which exceed 50% indicate that there was good precision of the soil inorganic concentrations.

VOCS. The precision of VOC concentrations for two water samples was assessed. These samples are WX121800 and WX420700. The only RPD value calculated that exceeded USEPA Region I guidelines was 1,2-dichloroethane for WX121800, which had a RPD value of 50%. The precision demonstrated by the laboratory for target VOCs was good.

The precision of soil VOC concentrations was measured using seven samples; BX410230, BXXJ0210, BXXH0512, BXXH1025, BXX00110, DX420900, and DX410800. One hundred sixteen of one hundred seventeen (99%) RPDs were 0%.

ABB Environmental Services, Inc.

APPENDIX E

The RPD calculated for acetone concentrations of DX410800 was 127%. Acetone was identified as a method blank contaminant in previous discussions. RPD data for soil VOC concentrations indicate that there was good precision of the nondetect results.

SVOCs. The precision of SVOC concentrations for two water samples were measured. These samples are WX121800 and WX420700. Only one RPD value calculated exceeded USEPA Region I criteria. Sample WX121800 had a RPD value of 54% for Caprolactam, a non-target compound. The data indicate that there was little variability of the target SVOC duplicate concentrations.

The precision of SVOC concentrations for seven soil duplicate samples was measured. These samples are BX410230, BXXJ0210, BXXH0512, BXXH1025, BXX00110, DX420900 and DX410800. RPDs for concentrations of detected SVOCs are summarized below:

COMPOUND	RPD RANGE
Bis (2-ethylhexyl)phthalate	0 to 64%
Di-n-butyl phthalate	0 to 148%
Fluoranthene	0 to 142%
Phenanthrene	0 to 138%
Pyrene	0 to 143%

Bis(2-ethylhexyl)phthalate and di-n-butyl phthalate were both identified as laboratory contaminants in the method blank discussion. The RPD values for fluoranthene, phenanthrene, and pyrene represent inconsistencies of the concentrations for samples DX410800 and BXXH0512. This may have been due to non-homogeneity of the compounds throughout the sample matrix and data should be considered estimated.

Explosives. Three duplicate water samples from Group 2 and 7 Study Areas were used to measure the precision of the concentrations of explosive compounds. These samples are MX1302X1, WX121800 and WX420700. One hundred percent of the RPD values were 0% indicating that the results were consistent in showing a lack of contamination with these compounds for the water sample.

APPENDIX E

Three duplicate soil samples from Group 2 and 7 Study Areas were used to assess the precision of concentrations of explosive compounds. These samples are BX410230, DX420900 and DX410800. One hundred percent of the RPDs were 0% indicating that there was good agreement of the concentrations of explosive results.

USEPA Methods. A precision assessment was also completed for concentrations of the following analytes: TOC, TPHC, TSS, alkalinity , bicarbonate ion, nitrate/nitrite, TKN, total phosphate, chloride ion and sulfate ion.

Five duplicate soil samples were used to determine the precision of TOC concentrations. These samples are BX410230, BXXJ0210, BXX00110, DX420900 and DX410800. RPDs of the concentrations of these samples ranged from 53% to 181%. This indicates a high degree of variability in TOC reported values and results should be considered estimated.

Four duplicate sets of soil samples were used to determine the precision of TPHC concentrations. The duplicate soil samples which were analyzed include BXXH0512, BXXH0125, BXXJ0210 and BXX00110. The RPDs of the TPHC concentrations for these samples ranged from 1.0% to 64%.

Seven water samples were used for the duplicate analysis of TSS concentrations. The samples used for this analysis are MX1302X1, MXXJ01X1, MX4103X1, MX4603X1, MXG308X2, MXXJ01X1, WX121800 and WX420700. RPDs for concentrations of these samples range from 0 to 43%.

One duplicate set of water samples was used to determine the RPD of alkalinity results. The water sample used for the duplicate analysis is MXG308X2. One of the duplicates had a detection of 6 $\mu\text{g/L}$ while the duplicate sample concentration was below the RL of 5 $\mu\text{g/L}$. Since the detection is so close to the RL, the difference of the results does not appear to be significant.

One duplicate set of water samples was used to determine the RPD of bicarbonate ion results. The sample used for precision analysis was MXG308X2. One of the duplicates had a detection of 7.3 $\mu\text{g/L}$ while the associated sample concentration was less than the RL of 6.1 $\mu\text{g/L}$. The RPD of the results is 18%.

APPENDIX E

Four duplicate set of water samples was used to determine the RPD of nitrate/nitrite results. The samples used for the precision analysis were MX1302X1, MXG308X2, WX121800 and WX420700. RPD values ranged from 0 to 128%.

Three duplicate sets of water samples were used to determine the RPD of total kjeldhal nitrogen results. The samples used for the precision analysis were MX1302X1, WD121800, and WX420700. RPD values ranged from 0 to 15%.

Three duplicate set of water samples was used to determine the RPD of total phosphate results. The samples used for the precision analysis were MX1302X1, WD121800, and WX420700. RPD values ranged from 8.8 to 21%.

Four duplicate set of water samples was used to determine the RPD of chloride ion results. The samples used for the precision analysis were MX1302X1, MXG308X2, WX121800 and WX420700. RPD values ranged from 0 to 15%.

Four duplicate set of water samples was used to determine the RPD of sulfate ion results. The samples used for the precision analysis were MX1302X1, MXG308X2, WX121800 and WX420700. RPD values ranged from 0 to 8.3%.

ASSESSMENT OF LOCATION-SPECIFIC APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS (ARARS) FOR FT. DEVENS, MASSACHUSETTS

1. INTRODUCTION

The Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) of 1980 was passed by Congress and signed into law on December 11, 1980 (Public Law 96-510). This act was intended to provide for "liability, compensation, cleanup, and emergency response for hazardous substances released into the environment and cleanup of inactive waste disposal sites." The Superfund Amendments and Reauthorization Act (SARA), adopted on October 17, 1986 (Public Law 99-499), did not substantially alter the original structure of CERCLA, but provided extensive amendments to it.

In particular, § 121 of CERCLA specifies that remedial actions for cleanup of hazardous substances must comply with requirements or standards under federal or more stringent state environmental laws that are applicable or relevant and appropriate to the hazardous substances or circumstances at a site. Inherent in the interpretation of applicable or relevant and appropriate requirements (ARARs) is the assumption that protection of human health and the environment is ensured. The purpose of this report is to supply a preliminary list of available federal and state location-specific ARARs that might be considered for Ft. Devens (FTD).

Location-specific requirements "set restrictions upon the concentration of hazardous substances or the conduct of activities solely because they are in special locations" (53 FR 51394). In determining the use of location-specific ARARs for selected remedial actions at CERCLA sites, one must investigate the jurisdictional prerequisites of each of the regulations. Basic definitions, exemptions, etc., should be analyzed on a site-specific basis to confirm the correct application of the requirements.

The following is an explanation of the terms used throughout this report:

Applicable requirements are "those cleanup standards, standards of control, and other substantive environmental protection requirements, criteria, or limitations promulgated under federal or state law that specifically address a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstances at a CERCLA site" (52 FR 32496, August 27, 1987).

Relevant and appropriate requirements are "those cleanup standards, standards of control, and other substantive environmental protection requirements, criteria, or limitations promulgated under federal or state law that, while not applicable to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a CERCLA site, address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well suited to the particular site" (52 FR 32496).

Requirements under federal or state law may be either applicable or relevant and appropriate to CERCLA cleanup actions, but not both. However, requirements must be both relevant and appropriate for compliance to be necessary. In the case where both a federal and a state ARAR are available, or where two potential ARARs address the same issue, the more stringent regulation must be selected. However, CERCLA §121(d)(4) provides several ARAR waiver options that may be invoked, providing that the basic premise of protection of human health and the environment are not

ignored. A waiver is available for state standards that have not been uniformly applied in similar circumstances across the state. In addition, CERCLA §121(d)(2)(C) forbids state standards that effectively prohibit land disposal of hazardous substances.

CERCLA on-site remedial response actions must only comply with the substantive requirements of a regulation and not the administrative requirements to obtain federal, state, or local permits [CERCLA §121(e)]. In order to ensure that CERCLA response actions proceed as rapidly as possible, the EPA has reaffirmed this position in the final National Contingency Plan (NCP) (55 FR 8756, March 8, 1990). Substantive requirements pertain directly to the actions or conditions at a site, while administrative requirements facilitate their implementation. The EPA recognizes that certain of the administrative requirements, such as consultation with state agencies, reporting, etc., are accomplished through the state involvement and public participation requirements of the NCP. These administrative requirements should be observed if they are useful in determining cleanup standards at the site (55 FR 8757).

In the absence of federal- or state-promulgated regulations, there are many criteria, advisories, guidance values, and proposed standards that are not legally binding, but may serve as useful guidance for remedial actions. These are not potential ARARs but are "to-be-considered" (TBC) guidance. These standards, etc., may be addressed in the text of this report as deemed appropriate.

2 LOCATION-SPECIFIC ARARs

Table 1 lists the major federal and state location-specific ARARs that might be pertinent to remedial actions at FTD. The text of some regulations under the Code of Massachusetts Regulations (CMR) were not available to the authors at the time of publication of this document. They will be referred to in the text based on sources who indicate their applicability and should be consulted should any of the relevant resources be present or suspected at a given remedial site. However, if the text is not available for analysis, the regulations will not appear on Table 1.

2.1. Faults

FTD is located in the Upland Subprovince of the New England Physiographic Province (EAISD 1991). This area is characterized by glacial deposits underlain by a complex of intensely folded and faulted metamorphic and igneous rock (EAISD 1991; ESE 1982). There are no faults with Holocene displacement under FTD (Sinnott 1992). However, the area has experienced a number of major earthquakes since the early 1700's that, while not involving fault displacement, have involved liquification of sediments (Sinnott 1992).

Under current RCRA regulations FTD is exempted from compliance with the RCRA seismic requirements of 40 CFR 264.18 since 264.18(a) stipulates that all facilities located within political jurisdictions other than those listed in Appendix VI are assumed to be in compliance for location of new treatment, storage or disposal (TSD) facilities. Massachusetts is not listed in the Appendix. However, EPA intends to propose additional seismic restrictions for location of TSD facilities [Notice of Proposed Rule Making (NPRM) March 1992; Final Rule expected March 1994]. At that time the new regulations may become applicable to FTD.

TABLE 1. Tentative Location-Specific Applicable or Relevant and Appropriate Requirements for FTD

Location Characteristic(s)	Operating Condition(s)	Requirement(s)	Citation(s)
Floodplains			
<ul style="list-style-type: none"> • Within 100-year floodplain • Treatment, storage or disposal facility <ul style="list-style-type: none"> • RCRA*-defined listed or characteristic hazardous waste (40 CFR 261) -or- RCRA-permitted facility 	<ul style="list-style-type: none"> • Federal agency action which involves: <ul style="list-style-type: none"> - acquiring, managing, and disposing of lands and facilities - providing federally undertaken, financed, or assisted construction and improvements - conducting federal activities and programs affecting land use 	<ul style="list-style-type: none"> • Facility must be designed, constructed, operated, and maintained to prevent washout of any hazardous waste by 100 year flood. • Federal agencies shall take action to reduce the risk of flood loss, minimize the impact of floods on human safety, health and welfare, and restore and preserve the natural and beneficial values of floodplains. • Federal agencies shall evaluate potential effects of actions in floodplains and ensure consideration of flood hazards and floodplain management. • If action is taken in floodplains, federal agencies shall consider alternatives to avoid adverse effects, incompatible development, and minimize potential harm. • Active portions of new treatment or storage facilities are prohibited within the boundary of land subject to flooding from the statistical 100-year frequency storm. • Active portions of landfills, land treatment units, surface impoundments, or waste piles are prohibited within the boundary of land subject to flooding from the statistical 500-year frequency storm. 	<ul style="list-style-type: none"> • 40 CFR 264.18(b) • Executive Order 11988 • 40 CFR 6.302(b) • 40 CFR 6 (Appendix A) • CMR tit. 310 § 30.701 • CMR tit. 310 § 30.700 • Hazardous waste subject to regulation under CMR tit. 310 § 30.000
<ul style="list-style-type: none"> • Inland and coastal land subject to flooding

2.2 Caves, salt-dome formations, salt-bed formations, and underground mines

FTD is located in north central Massachusetts in the counties of Middlesex and Worcester. The terrain is generally rolling to hilly (EAISD 1991; ESE 1982). The land surface consists primarily of unconsolidated glacial till, outwash and lake deposits (ESAISD 1991). FTD is underlain largely by glacial outwash sequences each with a diverse lithology (ESE 1982). There are no salt formations or caves on FTD (Shepherd 1992). In addition, there are no underground mines at FTD, although there are some gravel pits (Waugh 1992).

2.3. Floodplains and wetlands

FTD is located in the Nashua River Basin and the Nashua River flows through the installation (EAISD 1991; ESE 1982). Tributaries to the Nashua River, as well as numerous natural lakes and ponds, are located on FTD (EAISD 1991; ESE 1982; EEI 1992). There are also man-made impoundments on the installation (EAISD 1991). Given the extent of these resources, a complete catalogue is beyond the scope of this text. They are described in the *Master Environmental Plan for Ft. Devens, Massachusetts* (EAISD 1991) and the *Installation Assessment of Headquarters Ft. Devens* (ESE 1982).

There are several floodplains on FTD (Craig 1992). All along the portions of the Nashua River located within FTD are 100- and 500- year floodplains (Craig 1992). There are also 500- year floodplains around several of the water impoundments on the installation, including Robbins Pond and Mirror Lake (Craig 1992). To the west of Robbins Pond, there are 100- and 500- year floodplains along Cold Spring Brook. In addition, much of the entire South Post area is located within floodplains (Craig 1992). Given the abundancy of these resources, any specific site chosen for remedial action should be surveyed for floodplains.

Any remedial actions impacting floodplains would be subject to ARARs under 40 CFR 264.18(b), Executive Order 11988, 40 CFR 6.302(b), and 40 CFR 6 (Appendix A). In addition, Massachusetts hazardous waste facility location regulations, located at CMR tit. 310 § 30.701, would be ARAR. These latter regulations are framed in terms of facilities within the boundaries of land subject to flooding from the statistical 100-year and 500-year frequency storm, as well as differentiating between the active portions of different types of facilities, ie. new treatment or storage facilities, as opposed to landfills, etc. In addition, the removal, dredge, fill, or alteration of land subject to flooding is addressed at Massachusetts General Laws (MGL) ch. 131 § 40 and CMR tit. 314 § 9.01.

There are also numerous wetlands on and around FTD (Poole 1992a; EEI 1992; EAISD 1991; USFWS 1991; ESE 1982). Again, a complete description of all of these resources is beyond the scope of this text, but resource material is readily available in the sources cited in this section, as well as in National Wetlands Inventory Maps. Notably, the Oxbow National Wildlife Refuge is contiguous with the east-central portion of FTD (ESE 1982). This large wetlands area was deeded by FTD to the U.S. Department of the Interior (DOI) in 1973 (ESE 1982). In addition, wetlands along the Nashua River, as well as the Slaterock, Ponakin, and Cranberry Brook drainages have been identified by the Massachusetts Natural Heritage and Endangered Species Program's "Estimated Habitat Map of State-listed Rare Wetlands Wildlife" (USFWS 1991). Wetlands located on FTD along the Nashua River and its tributaries are also within one of Massachusetts' focus areas for wetlands habitats and resources (USFWS 1991). Clearly, any site chosen for remediation should be carefully surveyed for wetlands resources.

Any remedial activities that impact wetlands would develop ARARs under Executive Order 11990, 40 CFR 6.302(a), 40 CFR 6, Appendix A, Clean Water Act § 404, 40 CFR 230, and 33 CFR 320-330. Massachusetts regulations located at CMR tit. 310 § 30.705(6) prohibit location of the active portion of a landfill, land treatment unit, surface impoundment, or waste pile within a wetland. For the purposes of these regulations wetlands are defined according to MGL ch. 130 § 105, MGL ch. 131 § 40, or the regulations promulgated pursuant to those statutes. In addition, the dredge, fill, removal, or alteration of wetlands, wet meadows, etc. are controlled under MGL ch. 131 § 40 and wetlands protection is addressed at CMR tit. 310 § 10.01 *et seq.* The texts of the latter regulations are not available for full analysis at publication of this document. However, sources indicate that the requirements of these regulations are more stringent than their federal counterparts (Poole 1992a). For example, the regulations restrict actions that would affect wetlands to a distance of greater than 100 feet of the wetland boundary. The regulations have been ordered and will be analyzed in the next draft of this document.

2.4. Wilderness areas, wildlife refuges, wildlife resources, scenic rivers

There are no scenic rivers or wilderness areas on FTD, or within reasonable impact range of the installation. However, there is a wildlife refuge, the Oxbow National Wildlife Refuge, that abuts the east central portion of FTD (ESE 1982). This is a wetlands area that was once part of FTD, but was deeded to DOI in 1973 (ESE 1982). Any remedial action that could impact this resource would be subject to ARARs under the National Wildlife Refuge System Administration Act of 1966 (16 USC 668dd-ee), which requires that the effects of actions on the value of the wildlife refuge be considered.

There are also several state resources located in the vicinity of FTD. The Ayre State Game Area is located less than 1 kilometer north of the Moore Airfield (EAISD 1991). Lancaster State Forest is located to the west of the South Post area (EAISD 1991). Bolton Flats State Wildlife Management Area is located to the southeast of the South Post area (EAISD 1991). If any remedial activities appear likely to impact any of these areas, the appropriate state official and/or management personnel should be contacted for guidance as to any applicable requirements.

Given the broad range of natural resources and habitats on FTD, the presence of abundant and diverse wildlife resources is predictable. The draft report *Risk Assessment Approach for Shepley's Hill Landfill and Cold Spring Brook Landfill Site, Ft. Devens, Massachusetts* specifically details and characterizes the various terrestrial and aquatic ecosystems and their attendant wildlife (EEI 1992). Wildlife resources have also been summarized in a U.S. Fish and Wildlife Service (USFWS) report prepared for the U.S. House of Representative Appropriations Committee (USFWS 1991). A rich variety of resources are present at FTD and any site chosen for remediation should be carefully surveyed for wildlife resources and habitat. The impacts of any activity on these resources should be carefully considered.

Any remedial activity that results in the control of a natural stream or water body with fish or wildlife resources would be subject to ARARs under the Fish and Wildlife Coordination Act (16 USC 661 *et seq.*) and 40 CFR 6.302(g). Any action involving the discharge of dredge or fill material into an aquatic ecosystem with dependant fish, wildlife, other aquatic life, or habitat would dictate consideration of the Clean Water Act § 404, 40 CFR 230, and 33 CFR 320-220.

2.5. Rare, threatened, or endangered species

Although early information indicated no presence of rare, threatened, or endangered species at FTD, more recent studies and research have discovered a number of such species (ESE 1982; EEI 1992; USFWS 1991; Poole 1992c). For example, the peregrine falcon (*falco peregrinus*) and the bald eagle (*Haliaeetus leucocephalus*), both federally endangered species, have been observed at FTD during migration (Poole 1992c; USFWS 1991; EEI 1992). A current list of rare, threatened, and endangered species at the installation, provided by the Forestry, Fish and Wildlife Section at FTD, is reproduced in the Appendix of this report. In addition to those species, climbing fern (*Lygodium palmatum*), a state special concern species, has been documented within a 1.5 mile radius of the Shepley's Hill Landfill site (EEI 1992).

As part of an ongoing effort to monitor species at FTD there are currently several surveys and studies underway, or planned for this year, at the installation (Poole 1992a; Poole 1992b). An inventory of amphibians, reptiles, and their habitats being conducted at the FTD annex has documented a blue spotted salamander (*Ambystoma laterale*), which is a species of state concern (Poole 1992b; Poole 1992c). A radio-telemetry study of Blanding's turtle (*Emydoidea blandingii*) will begin this year (Poole 1992b; Poole 1992c). Two specialists are conducting surveys for butterfly species and a study of tiger beetles is underway (Poole 1992b; Poole 1992c). Finally, FTD is also sponsoring a survey for additional rare species, particularly bats and wetlands species (Poole 1992b; Poole 1992c).

Any site chosen for remedial action should be carefully surveyed for the presence of rare, threatened, or endangered species. If any are located, ARARs would develop under the Endangered Species Act of 1973 (16 USC 1531 *et seq.*), 50 CFR 402, 40 CFR 6.302(h), and the Fish and Wildlife Coordination Act (16 USC 661 *et seq.*). Moreover, if any activity involves the discharge of dredge or fill material into an aquatic ecosystem, the provisions of the Clean Water Act § 404 and 40 CFR 230.10(b) would also be applicable. Finally, ARARs would also derive from The Massachusetts Endangered Species Act (MGL ch. 131A § 1 *et seq.*) and its attendant regulations.

2.6. Archaeological resources and historic sites

There has not been a complete survey of FTD for archaeological resources (Simon 1992). However, sources at the Massachusetts Historical Commission indicate that there is approximately a 90% chance that such resources are present on the installation (Simon 1992). In addition, a historic district has been established around the parade field in the central portion of FTD (Winter 1992). The district includes the post headquarters, residential quarters, and barracks-type buildings constructed in the 1920's and the 1930's (Winter 1992). This district has been nominated to the National Register of Historic Places (Winter 1992; Simon 1992). The state has commented favorably on the nomination and the district will also be included on the comparable state list (Simon 1992).

A survey for archaeological resources and additional historic sites is warranted. If any are located and would be impacted by remedial activities, ARARs would develop under the Archaeological Resources Recovery Act of 1979 (16 USC 470aa-ll), 43 CFR 7, 32 CFR 229, the Archaeological and Historic Preservation Act (16 USC 469a-c), 40 CFR 6.301, and 32 CFR 650.181 *et seq.* In addition, the property in the historic district, or any other property that is eligible for the National Register of Historic Places or the National Historic Landmark Program, would be subject to ARARs under the National Historic Preservation Act (16 USC 470a-w), Executive Order 11593, 40 CFR 6.301, 36 CFR 800, and 32 CFR 650.181 *et seq.* ARARs may also develop under MGL ch.

9 §§ 26-27c, CMR tit. 950 §§ 70-71, MGL ch. 7 § 38A, MGL ch. 38 § 6(b), MGL ch. 30 §§ 61-62,
and CMR tit. 301 § 10.

Henslow's Sparrow	<i>Ammodramus henslowii</i>	FC, SE	?, l, **
Grasshopper Sparrow	<i>Ammodramus savannarum</i>	SC	b, m, t
Blackpoll Warbler	<i>Dendroica striata</i>	SC	m
REPTILES			
Blanding's Turtle	<i>Emydoidea blandingii</i>	ST	r
Spotted Turtle	<i>Clemmys guttata</i>	SC	r
Wood Turtle	<i>Clemmys insculpta</i>	SC	r
Eastern Box Turtle	<i>Terrapene carolina</i>	SC	r, #
AMPHIBIANS			
Blue-spotted Salamander	<i>Ambystoma laterale</i>	SC	r
Jefferson Salamander	<i>Ambystoma jeffersonianum</i>	SC	?, l
Marbled Salamander	<i>Ambystoma opacum</i>	ST	?, l

Four-toed Salamander	<i>Hemidactylum scutatum</i>	SC	?,
INVERTEBRATES			
Mystic Valley Amphipod	<i>Crangonyx aberrans</i>	SC	r
PLANTS			
Cattail Sedge	<i>Carex typhina</i>	ST	r
Midland Sedge	<i>Carex mesochorea</i>	SE	r
Houghton's Flatsedge	<i>Cyperus houghterii</i>	SE	r
Ovate Spike-sedge	<i>Eleocharis obtusa var. ovata</i>	SE	r
Blazing Star	<i>Liatris borealis</i>	FC	r

KEY

FE = Federal Endangered

SE = State Endangered

ST = State Threatened

SC = Special Concern (State category below threatened)

FC = Federal Candidate (Listed as a C1 or C2 candidate for inclusion on the endangered species list.)

r = resident; found year-round on the installation

b = breeds on the installation, may not stay year-round

? = no recent (>10 yrs.) records on site

l = local; records on similar habitats within 20 miles

m = migrant; remains one day or less during seasonal travel

t = transient; remains for 1 - 5+ days, any season

h = historical; records indicate species occurred on installation 10+ years ago

Species designated ?, l or h, l are subject to systematic census efforts to determine if the species occurs on the installation. For example, American Bitterns breed on the Oxbow National Wildlife Refuge adjacent to FTD. Efforts have been intensified to locate calling bitterns on similar habitats during breeding season.

* = Bald Eagle reintroduction efforts in Massachusetts have been very successful. There is a strong possibility that the Wachusett Reservoir and Nashua River Valley may be colonized by breeding pairs in the next 10 years.

** = Henslow's Sparrows may occur on site. Unconfirmed sightings are recorded on the drop zone and marshes.

= A Box Turtle was found on site in 1980. State officials believe it to be a released pet and not representative of a reproducing population.

NOTES:

- (a) U.S. Environmental Protection Agency (USEPA), SDWA National Primary Drinking Water Regulations per 40 CFR 141; MCLs and MCLGs.
- (b) USEPA, "Water Quality Criteria Summary," Office of Science and Technology, Health and Ecological Criteria Division, Washington, D.C.; May 1, 1991.
- (c) USEPA, "Drinking Water Standards and Health Advisories," Office of Water, Washington, D.C.; November 1991.
- (d) USEPA, "National Primary and Secondary Drinking Water Regulations; Synthetic organic Chemicals and Inorganic Chemicals; Final Rule", 57FR3177; July 17, 1992, effective January 1, 1994.

CWA = Clean Water Act TT = Treatment technique required.

continued

HA	=	USEPA Health Advisory	$\mu\text{g/l}$	=	micrograms per liter
MCL	=	Maximum Contaminant Level	$\mu\text{g/l}$	=	No federal or state guidance criteria or standards exist.
MCLG	=	Maximum Contaminant Level Goal	$\mu\text{g/l}$	=	No federal or state guidance criteria or standards exist.
(1)	MCL	for arsenic currently under review.			
(2)		Insufficient data to develop criteria. Value presented is the Lowest Observed Effect Level (LOEL).			
(3)		Standard indicated is the standard for total trihalomethanes (i.e., the sum of concentrations of chloroform, bromodichloromethane, dibromochloromethane, and bromoform). Refer to 56FR3579.			
(4)		Hardness dependent criteria (100 mg/l CaCO ₃ used).			
(5)		Proposed level, freshwater acute - 0.92 $\mu\text{g/l}$.			
(6)		Values presented are for trivalent species.			
(7)		Secondary standard based on aesthetics.			
(8)		Values presented are for hexavalent chromium species.			
(9)		Treatment technique action level 1,300 $\mu\text{g/l}$; secondary MCL is 1,000 $\mu\text{g/l}$.			
(10)		Treatment technique action level 15 $\mu\text{g/l}$; concentration measured at top.			
(11)		Nitrate or nitrite as nitrogen; standard total nitrate and nitrite is 10,000 $\mu\text{g/l}$.			
(12)		No more than 5% of the samples per month may be positive. For systems collecting fewer than 40 samples/month, no more than 1 sample/month may be positive.			
(13)		Values reported for chlordane (CAS # 57-74-9).			
(14)		Values reported for total PCBs (CAS # 1336-36-3).			
(15)

NOTES:

- (a) MADEP - Office of Research and Standards; Massachusetts Drinking Water Standards and Guidelines, (310 CMR 22.00) Massachusetts MCLs; Autumn 1992.
(b) MADEP - Division of Water Pollution Control; Massachusetts Surface Water Quality Standards, (314 CMR 6.06) Minimum GW Quality Criteria - Class I; promulgated December 31, 1986.
(c) MADEP - Division of Water Pollution Control; Massachusetts Surface Water Quality Standards, (314 CMR 4.05[b]) Class B criteria; promulgated July 20, 1990.
(d) MADEP; Massachusetts Drinking Water Standards; (310 CMR 22.05[8]) Maximum Microbiological Contaminant Levels; promulgated November 20, 1992.

DWS = Drinking Water Standards
MCLG = Maximum Contaminant Level Goal
MMCL = Massachusetts Maximum Contaminant Level
ORSG = Office of Research and Standards Guideline
 $\mu\text{g/l}$ = micrograms per liter
- = Standard not established.

- (1) MMCL established for 1,4-dichlorobenzene isomer (more stringent than for 1,2-isomer). Reported values are totals (isomers not distinguished.)
(2) Value is an Office of Research and Standards guideline.
(3) Standard indicated is concentration of total trihalomethanes (i.e., the sum of concentrations of chloroform, bromodichloromethane, dibromochloromethane, and bromoform).
(4) Defers to EPA DWS; see federal MCLs/MCLGs.
(5) Mean value per any set of samples.
(6) Defers to federal CWA Section 304(a); see federal AWQC.
(7) Numerical standard does not exist. MMCL is based on presence or absence of coliform.
(8) Nitrate as nitrogen.
(9) Value reported for chlordane
(10) Value reported for PCBs

Groups 2 and 7 Site Investigation
Fort Devens, Massachusetts

Analyte	Region III/ Residential Soil (a) (mg/kg)	Region III/ Commercial/ Industrial Soil (a) (mg/kg)	NYSDEC Sediment (b) (mg/kg)	NOAA Effects Range - Low Sediment (c) (mg/kg)	USEPA SQC (d) (mg/kg organic carbon)
nitroglycerine	-	-	-	-	-
Other					
nitrate/nitrite	30,000	1,600,000		-	-
TPH	-	-	-	-	-

NOTES:

- (1) Chromium IV values.
- (2) Dry weight.
- (3) Defers to USEPA SQC.
- (4) Values reported for chlordane (CAS # 57-74-9).
- (5) Values reported for total polychlorinated biphenyls (CAS # 1336-36-3). Memorandum from Roy L. Smith to RBC (Risk-Based Concentration) Table Mailing List, Subject: Risk-Based U.S. Environmental Protection Agency (USEPA) Region III, January 1993.
- (a) Concentration Table, First Quarter 1993; January 28, 1993.
- (b) NYSDEC Sediment Criteria (NYSDEC, 1989); Values reported for organic constituents must be carbon-normalized; Guideline value is lowest of Aquatic Toxicity or Wildlife residue basis.
- (c) National Oceanic and Atmospheric Administration (NOAA), March 1990. "The Potential for Biological Effects of Sediment-sorbed Contaminants Tested in the National States and Trends Program"; NOAA Technical Memorandum NOS OMA52; (Edward R. Long and Lee G. Morgan, authors)
- (d) USEPA, May 1988. "Interim Sediment Quality Criteria Values for Nonpolar Hydrophobic Organic Contaminants"; SDC#17.
- (e) USEPA OSWER Directive 193554-02.

mg/kg = milligrams per kilogram
 NOAA = National Oceanic and Atmospheric Administration
 NYSDEC = New York State Department of Environmental Conservation

SQC = Sediment Quality Criteria
 = No federal or state guidance criteria or standards exist.

DEVELOPMENT OF SURFACE SOIL PROTECTIVE CONTAMINANT LEVELS

No state or federal standards or guidelines exist for surface soil exposure, so this medium has been evaluated through comparison of maximum analyte concentrations in surface soils to benchmark values protective contaminant levels (PCLs) obtained through a computer-generated chronic exposure food web model. In order to establish conservative PCLs for the screening level PREs, an acceptable level of risk (Hazard Index [HI] equals 1) associated with chronic exposure to each surface soil analyte detected at Fort Devens was established.

The terrestrial food web model was developed to estimate the potential dietary exposure levels of contaminants for several potential receptor species representing various trophic levels within the ecological community at Fort Devens. Indicator receptor species were chosen to represent various taxonomic groups and trophic levels. It was assumed that each species evaluated is representative of other species within a given trophic level at Fort Devens (i.e., a trophic guilding approach was employed).

The following six indicator species were selected to represent exposure to terrestrial organisms via ingestion of food and surface soil at Fort Devens:

- Short-tailed Shrew (*Blarina brevicauda*). This carnivorous small mammal has a limited home range, a small body size, and a voracious appetite (Godin, 1977), factors which increase the likelihood that it will encounter significant environmental contaminant concentrations. Short-tailed shrews frequent woody regions with moist, loose humus, and can be found in marshes and meadows. The short-tailed shrew tends to avoid dry sites, and is active both day and night.
- White-footed mouse (*Peromyscus leucopus*). The white-footed mouse occupies a small home range of up to 0.5 acre in grassy fields. Though occupying a similar niche as the carnivorous short-tailed shrew, the white-footed mouse was chosen as an indicator species because it is primarily herbivorous, and is found in a variety of habitats, including deciduous, mixed, and carnivorous forests, clearings, pastures, streamside thickets, and around buildings (DeGraff and Rudis, 1983).

APPENDIX H

- American Robin (*Turdus migratorius*). This abundant passerine songbird occurs throughout open woodlands, forest edges, clearings, fields, and grassy areas. Robins forage on earthworms and insects, and may include fruits in their diet (DeGraaf and Rudis, 1983). They are frequently encountered in developed regions.
- Garter Snake (*Thamnophis sirtalis*). The garter snake was chosen to be representative of the reptile community at Fort Devens. This carnivorous snake feeds on small mammals, amphibians, and invertebrates, and has a home range of approximately 5 acres. Garter snakes occur in a variety of habitats, but are most common in the vicinity of wetlands.
- Red fox (*Vulpes vulpes*). This omnivorous mammal prefers open woodlands and grassy fields, and is most active in the night, and at dawn and dusk. It is an opportunistic predator, feeding on small mammals, birds, reptiles, amphibians, and invertebrates, as well as berries and other fruits (Burt and Grossenheider, 1976). The red fox has a home range of approximately 250 acres.
- Red-tailed Hawk (*Buteo jamaicensis*). This bird of prey prefers foraging in open country, frequently on woodland edges. It feeds primarily on small mammals, although invertebrates, reptiles, and small birds are also included in its diet.

Detailed information for each of the above species regarding diet, home-range, and other biological exposure parameters used in the food-web model are provided in Table I-1.

The food-web model was used to estimate contaminant levels in various primary prey items (e.g., invertebrates and plants) consumed by each receptor species. Estimated contaminant tissue residues in each prey species were estimated using specific bioaccumulation factors (BAFs) obtained directly or extrapolated from values in the scientific literature, as shown in the following equation:

$$\text{Prey Tissue Concentration (mg/kg)} = \text{Soil Concentration (mg/kg)} \times \text{Bioaccumulation Factor (BAF)}$$

APPENDIX H

Other BAFs were used to estimate tissue concentrations in secondary prey items such as small birds, rodents, and reptiles. Chemical-specific BAF values used in the food-web model are provided in Table I-2.

The potential dietary exposure (PDE) level, for each modeled receptor species, was calculated by multiplying each predicted prey species tissue concentration by the proportion of that prey type in the diet, summing these values, adding soil exposure, and multiplying by the Site Foraging Frequency (SFF) of the given receptor species. Incidental soil ingestion associated with foraging, preening, and cleaning activities, was conservatively assumed to represent five percent of total dietary intake. The PDE is represented by the following equation:

$$PDE = \sum_{1 \rightarrow n} [P_1 \times T_1 + P_2 \times T_2 + \dots + P_n \times T_n + \text{soil exposure}] \times SFF$$

where:

PDE	= Potential dietary exposure (mg/kg)
P_n	= Percent of diet composed of prey item n
T_n	= Tissue concentration in prey item n (mg/kg)
Soil Exposure	= (0.05)(Soil concentration in mg/kg)
SFF	= Site Foraging Frequency; Area of Contaminated Soil (acres)/Home range (acres)

Finally, the potential dietary exposure for each receptor species was multiplied by the receptor-specific ingestion rate and divided by the estimated body weight to calculate a Total Body Dose (TBD):

$$TBD = PDE \times IR \times \frac{1}{BW}$$

where:

TBD	= Total Body Dose (mg/kgBW-day)
PDE	= Potential dietary exposure (mg/kg)
IR	= Ingestion rate (kg/day)
BW	= Body weight (kg)

Because the TBD estimates are normalized to the ingestion and body weight of the particular receptor being evaluated, they are directly comparable to estimated Reference

APPENDIX H

Toxicity Values (RTVs) values derived from the literature. The comparison of the TBD estimate with the appropriate RTV results in an index (the Hazard Index) of potential impact associated with exposure to that particular chemical.

Toxicity data evaluated for terrestrial receptors consists of acute and chronic oral ingestion studies which were preferentially chosen in the following order: 1) feeding studies, 2) gavage studies, 3) drinking water studies. Based on these data, RTVs were developed to represent a threshold dosage for effects to terrestrial organisms. RTVs are expressed in mg/kg BW (body weight)/day (dose normalized to body weight). From the toxicological data set evaluated (Table I-3), compound-specific chronic toxicity values for each type of receptor (indicator species) were selected as the Fort Devens RTVs. These RTVs are presented in Table I-4.

The RTV selection procedure included the following general guidelines:

- Taxon-specific toxicological data were used whenever possible, regardless of study status (acute vs chronic, etc). When taxon-specific data were unavailable, available toxicological data were applied to the indicator species. Because reptile toxicological data are scarce, bird toxicity values were used to represent garter snake RTVs.
- Chronic RTVs are based on the average of reported Lowest Observed Adverse Effect Levels (LOAEL) for non-mortality endpoints from chronic studies (i.e., those lasting >364 days). However, when chronic non-mortality data were unavailable, the average of reported LOAEL non-mortality data from sub-chronic studies (those lasting 15-364 days) were used for the RTV. Mortality data from chronic studies were used only when data from chronic or sub-chronic non-mortality studies were unavailable. LOAELs extrapolated from acute or No Observable Adverse Effect Levels (NOAEL) were not included when LOAELs were averaged to derive RTVs.
- When chronic or sub-chronic studies were not available, acute study values were used. In these cases, two factors are applied to the acute Lethal Dose Fifty (LD_{50}) (the single dose lethal to 50 percent of the test organisms). These include: (1) a factor of 0.2 for extrapolating from the oral LD_{50} to a value expected to protect 99.9 percent of the population from acute effects (USEPA, 1986); and (2) a factor of 0.1 for extrapolating

from acute to chronic values (the acute-chronic ratio for many chemicals is approximately 10 (Newell et al., 1987)). Additionally, in cases where only a NOAEL value was available, a factor of 5 was used to extrapolate an estimated LOAEL from the NOAEL value. LOAELs extrapolated from chronic or sub-chronic NOAEL data were preferentially used over data extrapolated from acute studies.

- When no studies were available in the ABB-ES data base for a given contaminant, the contaminant was assigned an appropriate surrogate chemical for which adequate toxicological data exists (i.e., benzo(a)pyrene was used as a surrogate for dibenzo(a,h)anthracene).

Development of Protective Contaminant Levels (PCLs)

In order to develop PCLs, an acceptable level of risk associated with exposure to each contaminant (Hazard Index [HI] = 1) was multiplied by the particular contaminant-specific RTV to estimate a Target Intake Dosage (TID), expressed as mg/kgBW-day, as shown by the following equation:

$$\boxed{TR \times RTV = TID}$$

TR = Target Risk (HI = 1.0)
RTV = Reference Toxicity Value (mg/kgBW-day)
TID = Target Intake Dosage (mg/kgBW-day)

The TID was multiplied by the Dietary Contribution Factor (DCF) (the inverse of the equation used to derive TBD) to estimate the PCL of the particular contaminant, as shown by the following equation:

$$\boxed{TID \times DCF = PCL}$$

TID = Target Intake Dosage (mg/kgBW-day)
DCF = Dietary Contribution Factor (kgBW-day/kg)
PCL = Protective Contaminant Level (mg/kg)

APPENDIX H

PCLs were developed for all analytes for each of the six terrestrial receptor organisms evaluated through the food web model. The lowest resultant PCLs were selected as the PCL values for use in these PREs; these PCLs are presented in Table 3-5 (in report text). For the majority of the contaminants evaluated, the short-tailed shrew (due to its small home range, voracious appetite, and insectivorous diet) was found to be the ecological receptor species with the lowest PCL. The PCL values used in the risk evaluation represent the concentration of each analyte in surface soil that, if not exceeded, is protective of all terrestrial organisms, including the short-tailed shrew. Because suitable habitat for the shrew does not exist at several Groups 2 and 7 SAs, additional details regarding the use of alternative PCLs is presented in the individual PREs.

Because of the numerous conservative assumptions included in the chronic exposure risk assessment model, the lowest PCL for four inorganic analytes (aluminum, barium, lead, and vanadium) are below their respective background concentrations established for Fort Devens. For these four analytes, the background concentration (rather than the PCL generated through the food web model) was used as the screening tool for evaluating surface soil at the Groups 2 and 7 sites. Collecting, the computer-generated PCLs and the background concentrations for these 4 analytes are referred to as surface soil benchmark values in the Fort Devens PREs. In general, the benchmarks developed through this approach are at least as conservative as available guidelines for evaluating surface soil contamination (i.e., Fitchko, 1989; Beyer, 1990).

PRE GENERAL ASSUMPTIONS AND UNCERTAINTIES

ASSUMPTIONS AND UNCERTAINTIES

General assumptions and uncertainties for the Fort Devens PREs include, but are not limited to, the following:

1. The human health standards and guidelines used in these PREs are based on standard USEPA exposure assumptions. Quantitative human health risk assessments based on SA-specific characteristics and exposure potential have not been conducted.
2. The USEPA Region III Risk-Based Concentrations are readily available screening values used in the human health PREs. They do not represent target cleanup levels. Because they are based on standard USEPA risk assessment assumptions and methodology, the risk-based concentrations are considered to be reasonable screening values.
3. The food web models used to estimate surface soil protective concentrations involve numerous exposure parameters, some of which are values from the literature, and some of which are assumed or estimated. Efforts were made to select exposure parameters representative of a variety of species or feeding guilds, so that exposure estimates would be representative of more than a single species. However, numerous extrapolations relating measurement and assessment endpoints have been included in these PREs. These include extrapolations between taxa, between responses, and from laboratory to field studies.
4. The exposure models from which protective surface soil levels were derived assume that organisms will spend equal amounts of time in all habitats within their home ranges. In actuality, organisms will spend varying amounts of time in different habitats which would affect their exposures. The limitation of this assumption is that exposures to the particular species modeled may be over-estimated or under-estimated in these PREs.
5. Information regarding the presence or absence of ecological receptors at the site was obtained from a review of literature, habitat characteristics, and short-term field studies. Actual occurrence and/or utilization of the site by many ecological receptors is uncertain.

APPENDIX H

6. Neither dermal contact nor inhalation were evaluated in the protective surface soil food web model because of a lack of information concerning uptake rates for wildlife. Therefore, total ecological exposure may be greater than predicted based solely on modeled ingestion scenarios. However, the relative contribution of dermal contact to total ecological risk is expected to be much lower than that of food and sediment ingestion, because of the protective fur, feathers, or hardened skin covering most species of semi-terrestrial wildlife.
7. The PREs evaluate potential ecological effects to individual organisms, and do not evaluate potential population-level risks. In many circumstances, acute or chronic effects may occur to individual organisms with little potential population or community level effects; however, as the number of individual organisms experiencing toxic effects increases, the probability that population-level effects will occur also increases. As a result of this assumption, the calculated protective concentrations may be overly protective of community or population level effects.
8. An assumption was made that all analytes in the Fort Devens surface soil and surface water are bioavailable, and that all inorganics in sediments are bioavailable. In actuality, it is likely that only a portion of these analytes are bioavailable; therefore, these PREs may over-estimate risk.
9. The PCLs developed through the back-calculated food web model represent a screening tool to determine whether or not an analyte may present risk to ecological receptors. These PCLs do not represent target cleanup levels.

NOTES:

[a] Bio-accumulation Factors (BAFs) were conservatively estimated to be 1 when empirical data were unavailable.

Plant BAFs were set equal to 1 when equation presented in [c] exceeded 1.

[b] Calculated using the following equation in USEPA (1990) unless otherwise indicated:

$$\log(\text{Plant Uptake Factor}) = 1.588 - 0.578 \log \text{Kow}$$

[c] Value from USEPA (1990).

[d] From USEPA (1985).

[e] From Verschueren (1983).

[f] From Eisler (1987).

[g] Value from Hansch and Leo (1979).

[h] Geometric mean of values reported for various plant species in USEPA (1985)

[i] Geometric mean of values for earthworms, beetles, and slugs reported in USEPA (1985)

[j] BAF value for earthworms from Diercxens et al (1985)

[k] Plant value from Eisler (1988).

[l] Mammal value from USEPA (1985).

[m] Bird value from USEPA (1985)

[n] Conservative BAF estimation in excess of 1.

[o] Values for earthworms and small mammals from McFadyen (1980).

[p] Plant value from USEPA (1985).

[q] Earthworm and chicken value from USEPA (1985).

[r] Mammal value from USEPA (1985).

[s] Invertebrate, mammal, and bird value from USEPA (1985)

[t] Plant and small mammal value from USEPA (1985).

TABLE H-3
SUMMARY OF INGESTION TOXICITY DATA FOR TERRESTRIAL WILDLIFE (REFERENCE TOXICITY VALUES)
SITE INVESTIGATION REPORT
FORT DEVENS

CHEMICAL	TEST SPECIES	TEST TYPE	DURATION	EFFECT	ACUTE*		CHRONIC*					
					ORAL LD50 (mg/kg DWY)	RISK CRITERIA (mg/kg BW)	NOAEL LOAEL (mg/kg BW/day)	NOAEL (mg/kg BW/day)				
NOTES:												
[a] For chemicals lacking LOAEL or NOAEL data, an Acute Oral Criterion (AOC) is calculated by applying a factor of 0.2 to the acute LD50; this value is expected to protect 99.9% of the exposed population from acute effects (USEPA, 1986).												
[b] Estimated by applying an acute - chronic ratio of 10.												
[c] Converted to dose per kilogram body weight by multiplying by ingestion rate and dividing by body weight.												
The following ingestion rate and body weight data were used:												
Species	Ingestion Rate (kg/day)	Body Weight (kg)	Reference									
Rat (Male)	0.025	0.58	USEPA, 1988									
Rat (Female)	0.02	0.25	USEPA, 1988									
Rat	0.015	0.25	NIOSH, 1985									
Rabbit	0.059	2.2	USEPA, 1988									
Chicken	0.106	1.16	USEPA, 1988									
Bobwhite	0.015	0.17	Kemaga, 1973									
California quail	0.014 [e]	0.139	USEPA, 1988									
Mallard Duck	0.09	1.25	Terres, 1980									
Duck	0.112 [e]	1.6	USEPA, 1988									
Starling	0.01	0.0437	USEPA, 1988									
Kestrel	0.01	0.179	USEPA, 1988									
Screech Owl	0.0006	0.169	USEPA, 1988									
Mink	0.0465	1.613	USEPA, 1988									
Mouse	0.0035	0.03	USEPA, 1988									
Dog	0	14.47	USEPA, 1988									

[d] Estimated by applying a LOAEL - NOAEL ratio of 5 (Newell et al., 1987).

[e] Ingestion rate estimated from body weight using allometric equation for chicken as in USEPA, 1988.

[f] Chrysene data used as surrogate for benzo(a,h,i)perylene

BW = Body Weight

LOAEL = Lowest Observed Adverse Effect Level

NOAEL = No Observed Adverse Effect Level

NOTES:

[a] All values are chronic Lowest Observed Adverse Effects Levels (LOAELs), unless otherwise noted.

Values were obtained from the master Reference Toxicity Values (RTVs) summary table (H-3) following procedures described in text.

[b] Average of LOAEL bird values.

[c] Average of LOAEL values.

APPENDIX I

SYNOPTIC WATER LEVEL DATA SUMMARY

ABB Environmental Services, Inc.

APPENDIX I
SUMMARY OF SYNOPTIC WATER-LEVEL MEASUREMENTS

ABB-ES conducted synoptic water-level rounds on May 26, September 15, and December 22 of 1992, March 30 and November 8, 1993, and March 30 and June 28, 1994. The number of measuring points varied because new measuring locations were added by the SI and SSI program and because certain stations were not accessible or not measurable. The number of water-level stations were as follows:

All measured water-levels are tabulated below.

APPENDIX I
SYNOPTIC WATER-LEVEL MEASUREMENTS

APPENDIX L

GEOPHYSICS REPORT

ABB Environmental Services, Inc.

W0039366APP.CVR

7053-07

INTRODUCTION

The purpose of this appendix is to describe the geophysical surveys which took place at Fort Devens during the SI and SSI, included in SA 43 (19 historic gas stations and the central gasoline-distribution sites) at the sites, all of which are located in the Main Post and SA 41 located in the South Post. The purpose for these investigations was to

- search for and accurately locate abandoned USTs and associated piping; and
- clear underground utilities for tank excavation and soil borings;
- identify potential groundwater contaminant source areas.

Several geophysical techniques were employed during this field efforts. These include ground penetrating radar (GPR), metal detector, terrain conductivity and magnetometry.

SCHEDULE

The SI geophysical survey took place between April 27 and May 21, 1992.

PERSONNEL

The following ABB-ES personnel participated in the SI geophysical survey:

- R. Allen (Sr. Geophysicist)
- D. Lovejoy

SURVEY CONTROL

All SI surveys were conducted in a general reconnaissance mode (no formal survey grid except as noted in the following discussions for each site) in an area of approximately one acre around each station. Any USTs which were located were accurately marked in the field in anticipation of subsequent excavation efforts. At any site where tanks are believed to remain in place but could not be located by geophysical techniques within approximately 120 feet (the approximate radius of a

ABB Environmental Services, Inc.

1-acre area) of their suspected locations, it was assumed that they were previously removed.

FIELD PROCEDURES

A total of 14 sites were investigated under the SI survey. They are: SA 43A, SA 43B, SA 43C, SA 43D, SA 43E, SA 43G, SA 43H, SA 43I, SA 43J, SA 43K, SA 43N, SA 43Q, SA 43R, and SA 43S (Figure 1). Other sites described in the work plan were eliminated due to information which was discovered after the work plan was prepared.

ABB-ES established survey traverse lines in the field considering available data on tank, piping, and former pump island locations and access limitations. A metal detector (MD) screening of the site in the assumed location of the USTs was performed initially at each site. This was followed by GPR profiling of MD anomalies. This methodology often permitted the location and subsequent mapping of a UST in a very efficient manner. If the GPR data did not indicate the presence of a UST or associated piping at a MD anomaly, a magnetometer survey was initiated on a 10- by 10-foot grid over an area centered on the presumed location of the UST provide additional assurance that the UST had not been inadvertently overlooked. Any magnetic anomalies were then investigated with GPR.

The locations for soil borings were cleared with GPR and marked in the field.

METAL DETECTOR SURVEY

Metal detection techniques are often used in hazardous waste and related studies to map the edges of trenches where hazardous materials may have been disposed in drums or other metallic containers, to trace underground utilities, to locate buried tanks, and to quickly screen large sites where metallic deposits are known or suspected. Once a general site screening has been performed, investigators are in a better position to formulate a strategy for additional exploration techniques, as appropriate.

A metal detector responds to the electrical conductivity of metal targets. The conductivity of such targets usually contrasts sharply with that of the medium surrounding them (air or soil). Although there are many different types and

ABB Environmental Services, Inc.

configurations of metal detectors, all of them consist of a transmitter and receiver. The transmitter creates an alternating (primary) magnetic field about the transmitter coil which is balanced, or nulled, in the receiver coil to cancel the effect of the primary field in the transmitter. When the transmitter is in the vicinity of a metal object, eddy currents are induced to flow in that object by the primary field generated by the transmitter. These eddy currents produce a secondary magnetic field which interacts with the primary field upsetting the existing balance (null) condition resulting in an output, normally to a meter or audio signal, or both.

At each of the historic gas station sites, the metal detector was used during the initial survey to confirm that the site is not underlain by large amounts of metallic debris.

GROUND PENETRATING RADAR SURVEY

The GPR technique uses high frequency radio waves to determine the presence of subsurface objects and structures. Energy is radiated downward into the subsurface from an antenna that is pulled slowly across the ground at speeds varying from about 0.25 to 5 mph, depending on the amount of detail desired and the nature of the target. The radio wave energy is reflected from surfaces where there is a contrast in the electrical properties of subsurface materials. These surfaces may be naturally occurring geologic horizons (e.g., soil layers, changes in moisture content, voids and fractures in bedrock) or manmade (e.g., buried utilities, tanks, drums). The reflected energy is processed and displayed as a continuous strip chart recording of distance versus time (where time can be thought of as proportional to depth). The depth of penetration of a GPR system is highly site-specific, and depends on the soil types at the site (clean sands are best), moisture conditions (dry is best), and the frequency of the antenna (the lower the frequency, the deeper the penetration, and the less the resolution capability).

Typical applications for GPR include delineating the boundaries of buried hazardous waste materials and the perimeters of abandoned landfills; finding steel reinforcement bars and voids in concrete structures; and locating and mapping underground storage tanks and other buried utilities.

MAGNETOMETER SURVEY

Magnetometers are used routinely for locating repositories of buried (drummed) wastes. Locating and quantifying these materials is essential to any remediation effort, and magnetometer surveys can provide an extra measure of safety to those personnel involved in the clean-up activities.

The earth's magnetic field is modified locally by both naturally occurring and manmade magnetic materials. The total field of the earth has a value which varies from approximately 30,000 to 60,000 gammas, depending on location: the total field value is approximately 30,000 gammas at the equator and 60,000 gammas at the poles. One can obtain the absolute value of the total earth's field intensity to an accuracy of 1 gamma or better. In the field, the operator should be aware of sources of high magnetic gradients such as would be caused by power lines, buildings, and any large iron or steel objects. If a total field survey is being conducted, base station readings should be taken frequently (every 30 minutes to 1 hour) to provide a check on any diurnal variations and magnetic storms that may occur during a survey. Typically, diurnal variations will not exceed a few tens of gammas.

Vertical gradient measurements involve the simultaneous acquisition by two sensors of two values of the total field. For this study, an EDA Omniplus Vertical Gradiometer was used. The sensors are mounted on a staff that is held vertically during a measurement. A known distance (in this case $\frac{1}{2}$ meter) separates the sensors on the staff. The upper sensor is 8 feet above the ground when a measurement is taken. This instrument records all data in an internal memory which can be transferred in the field to a personal computer for evaluation and data processing. The vertical gradient value is derived by obtaining the difference between the total field values of the lower and upper sensors divided by the distance between them.

Vertical gradient measurements are more sensitive to the presence of near-surface metal objects than total field values alone and are not subject to diurnal magnetic variations because any variation affects the two sensors on the magnetometer sensor staff equally.

RESULTS

The results are discussed site by site below. A total of eight USTs were mapped during this investigation, and plans have already been implemented to excavate these structures and remediate the soil surrounding the tanks as necessary.

Site 43A. This site is the former central distribution facility for the historic gas stations. It was located in what is now the Petroleum, Oil, and Lubricant (POL) Storage, across Market Street from the Defense Reutilization Marketing Office (DRMO) between Antietam, Cook, and Market Streets. Due to the presence of chain link fences, railroad tracks, and power lines, a magnetometer survey over the entire site was not feasible, so a metal detector screening survey was conducted. The spacing between adjacent traverses was from 3 to 5 feet. The entire site was screened in this manner. Eight anomalous zones were mapped and flagged in the field with the metal detector (Figure 2), and each of these were each studied by either magnetometer or ground penetrating radar, or both. For several of the MD anomalies where the magnetometer could be used, a series of spot readings were taken. USTs generally reveal themselves with vertical gradient values of approximately 1000 gammas per meter. There were no indications of USTs for any of these anomalous zones, although the soils in the vicinity of the railroad were impenetrable by the GPR energy, presumably due to the materials used as ballast in the railroad bed.

A magnetometer survey was conducted in the vicinity of the MD anomaly in the northwest corner of the site near the corner of Market and Cook Streets (see Figure 2). Both the metal detector and GPR were ineffective due to the materials in the railroad bed. The vertical gradient contours for this survey are presented on Figure 3. A total of 59 magnetometer stations were established on a 10- by 10-foot measurement grid. The data do not indicate the presence of a UST, although there could be some piping or other metallic objects buried in this general area causing the several high vertical gradient values observed here.

Site 43B. The foundation for the old pump house and pump island is still evident at SA 43B across Patch Road from Building 3545. MD and GPR were used initially to quickly determine if any USTs remain at this site. When the results of this initial screening were negative, a magnetometer grid was laid out and a magnetometer survey (10- by 10-foot grid) was completed (Figure 4). A total of

178 magnetometer stations were established. The results of the magnetometer survey are presented as Figure 5. No USTs are believed to be present at this site.

Site 43C. The foundation for the old pump house and pump island off Patch Road is still evident at SA 43C. MD and GPR were used initially to quickly determine if any USTs remain at this site. GPR confirmed the presence of a single UST which was marked in the field between Building 3541 and the pump island (Figure 6).

Site 43D. The foundation for the old pump house and pump island is not evident at SA 43D off Patch Road. MD and GPR were used initially to quickly determine if any USTs remain at this site. GPR confirmed the presence of two USTs which were marked in the field straddling a chain link fence (Figure 7). One of the USTs was partially beneath a steel dumpster.

Site 43E. SA 43E is located on the parking lot of the Shawmut Bank near Building 2000 on MacArthur Avenue. MD was used to quickly screen the parking lot, locating an anomaly which was subsequently studied with GPR. GPR confirmed the presence of a UST in the parking lot, which was mapped and marked by the field party (see field sketch, Figure 8).

Site 43G. Located off Queenstown Street near Building T-2009, a GPR survey was completed with traverses separated by 3 feet (Figure 9). This work did not identify a UST. A magnetometer survey was not feasible due to the presence of a chain link fence, two dumpsters, a metal storage building, and several vehicles.

Site 43H. Located in the driveway of the motor pool (Building 602) on Queenstown Street, a GPR survey was completed on a 5-foot grid in both directions (Figure 10). No USTs were mapped at this location.

Site 43I. A GPR survey between Queenstown Avenue and Building 603 did not identify a UST at SA 43I. GPR traverses were separated by approximately 3 feet and were run in both directions (Figure 11).

Site 43J. A UST was identified and marked by a MD/GPR survey in front of two hazardous waste storage buildings near Building T-2446 across Patton Street from a cemetery (Figure 12).

Site 43K. GPR profiling off Patton Street adjacent to Building 2514 resulted in the identification and mapping of an UST (Figure 13).

Site 43N. Located on Lake George Street by a former wash rack, a single UST was located and mapped with MD/GPR (Figure 14). A magnetic survey was also completed to locate a second tank which might still exist. The second UST was not found. The results of the magnetometer survey are shown on Figure 15. A total of 113 magnetometer stations were established.

Site 43Q. A metal detector was used to quickly screen SA 43Q, located on the soccer field off Sherman Avenue. Several MD anomalies were located, and GPR profiling did not indicate the presence of USTs. A magnetic grid was then set up to extend the geophysical coverage to determine if a UST was located outside of the primary presumed location for an UST (Figure 16). A total of 437 magnetometer stations were established. The results of the magnetic survey are presented as Figure 17. Several GPR traverses were completed in the vicinity of several moderately high magnetic anomalies, resulting in no USTs being identified.

Site 43R. This former gas station site is located northeast of the soccer field (SA 43Q) and across Sherman Avenue from Building 696. A magnetometer survey was completed in the southwest corner of a several acre field adjacent to the parking lot. A total of 348 magnetometer stations were established (Figure 18). The results of the magnetometer survey are presented as Figure 19. A GPR survey was then conducted in the vicinity of a large magnetic anomaly, confirming the probable presence of a UST 15 to 18 feet long. This structure was marked and flagged in the field. Figure 20 shows the location of the UST with respect to fixed landmarks at SA 43S.

Site 43S. Located west of the Nashua river on Gorgas St. near Building 3412, a metal detector survey was used to quickly determine if UST(s) were still present. That screening effort was not conclusive, so a magnetometer survey was completed in an area 200 feet by 150 feet (see Figure 20). A total of 477 magnetometer stations were established. The results of the magnetometer survey are presented as Figure 21. No magnetic anomalies indicating USTs were noted during this effort.

STUDY AREA 41 GEOPHYSICAL SURVEY**INTRODUCTION**

The original objectives of the SSI geophysical survey completed at SA 41 were to delineate the limits of the landfill and provide information on potential groundwater contaminants source area. The SSI survey effort was performed during the SA 41 field program in September 1993.

SURVEY METHODS

Two geophysical surveying techniques, magnetometry and terrain conductivity, were selected as the most appropriate methods to meet the objectives of the SA 41 SSI. A rectangular X-Y grid system was established within the survey area in 1993 along which SSI geophysical survey data was collected. The surveyed area is presented in Figure 22.

Because the survey area is adjacent to an active firing range, unexploded ordnance (UXO) clearance was deemed necessary prior to geophysical surveying. Before geophysical surveying started, vegetation was removed along survey lines during UXO clearing activities to allow easier access to the grid nodes. During all phases of geophysical surveying, ABB field personnel were escorted by an ABB-ES subcontractor certified to provide UXO services.

Field maps were generated during geophysical survey data collection for the purpose of locating survey stations, cultural landmarks, and natural and man-made surface features within the survey area.

MAGNETOMETER SURVEY METHOD

The magnetometer survey method is used to measure variations in the earth's natural magnetic field strength resulting from the localized effects of natural and man-made materials. Man-made materials that can affect the earth's magnetic field include objects constructed of ferrous metal (steel and iron). Nonferrous metal objects, such as those constructed of aluminum, copper, and tin, do not effect magnetic fields and are thus not detectable with a magnetometer.

The magnetic gradiometer, a type of magnetometer, is a portable instrument consisting of a pair of total field sensors mounted on a survey pole. The sensors are designed to measure the earth's magnetic field strength (usually in gammas) simultaneously at each sensor while the survey pole is held vertically. The vertical magnetic gradient (measured typically in units of gammas/meter) can then be determined by calculating the difference between the total field values measured by each sensor and dividing that value by the distance separating the two sensors. Because the total field is measured during a sampling event, both the gradient and total field values can be used together during the interpretation of survey results.

Anomalous, localized variations in the normal total field or vertical magnetic gradient values are often attributable to both surface and subsurface ferrous metal objects. The magnetic field strength and vertical magnetic gradient values are proportional to the mass of the ferrous metallic source and inversely proportional to the cube of the distance between sensor and object. Based on this, the size and proximity (depth of burial for subsurface objects) of the target will influence the response of the magnetometer.

The effectiveness in interpreting data collected with this survey method is dependent on understanding two important factors that affect the data. The first, and perhaps most important in locating subsurface targets is the interference caused by the presence of natural and cultural features at the surface (automobiles, fences, overhead utility lines, bedrock outcrops, and time-variable changes in the earth's magnetic field). For this reason, it is particularly important to note all surface physical features within the survey area that may influence the data. The second factor to consider is the natural variation of the earth's magnetic field strength. Significant changes can take place over a matter of hours. Monitoring these natural variations at a selected base station during the survey allows the interpreter to factor these variations out of the data set if necessary. One beneficial feature of magnetic gradient data is that these natural variations do not affect the data because they are factored out in the calculation. Magnetic gradient data tend to be less sensitive to magnetic field noise.

Total field and magnetic gradient data can be measured at discrete locations (usually within an X-Y survey grid). The X and Y horizontal coordinates and the magnetometer values are then used to generate total field and vertical gradient contour maps of the survey area. By factoring out the effects of surface

interference and natural variations in field strength, anomalies in the total field and vertical magnetic gradient produced by buried ferrous metal objects can be seen in the contour maps. The anomalies can then be used to make assumptions on the location, size, distribution, and occasionally the depth of ferrous metal targets.

TERRAIN CONDUCTIVITY SURVEY METHOD

The terrain conductivity survey method (also known as an electro-magnetic induction or EM survey) measures electrical conductivity in subsurface materials. Variations in conductivity can be the result of several natural factors including soil type, porosity, moisture content, and pore water salinity. Buried waste and metal utility lines can also produce measurable variations in subsurface conductivity. The terrain conductivity survey provides a good interpretation supplement to the magnetometer survey in that metallic objects (ferrous and nonferrous) and conductive materials are detectable. The combination of both surveys provides a particularly effective remote sensing tool for buried waste materials.

The typical terrain conductivity survey unit is comprised of portable sending and receiving electromagnetic field coils. The 3-dimensional source field produced by the unit induces electrical eddy currents in subsurface materials that in turn produce a secondary electromagnetic field. This secondary magnetic field is received by the terrain conductivity unit where the field strength is measured and recorded in a portable data logging device. The magnitude of the secondary field is roughly proportional to the conductivity of subsurface materials beneath the sampling point. When collected in a survey mode, as conductivity values are recorded from one location to another, these values provide an indication of the relative changes in subsurface material composition.

Near surface variations in conductivity values are most easily detected with this survey method. As with the magnetometer survey, the quality of terrain conductivity data can be adversely affected by the presence of surface features such as fences, automobiles, and electromagnetic noise produced by overhead power lines, radio transmitters, and atmospheric conditions.

The two components (quadrature phase and in-phase values) of the secondary electromagnetic field produced while conducting a terrain conductivity survey can be measured during the data collection. The quadrature phase (real solution)

component represents the terrain conductivity value averaged over the range of the primary field, and the in-phase (imaginary solution) component is essentially equivalent to a metal detector response.

Terrain conductivity data can be collected at discrete stations (i.e., grid nodes) in much the same manner as the magnetometer data is collected. Data is processed into conductivity contour maps, and anomalies interpreted. The anomalies can then be used to make assumptions on the location, size, distribution, and occasionally the depth of electrically conductive media.

SA 41 MAGNETOMETER SURVEY

The magnetometer survey was conducted using a GEM™ gradiometer. The unit consists of a portable microprocessor-based proton precession magnetometer with a pair of proton precession total field magnetic sensors mounted on a vertical survey pole. With the pole held vertically, the magnetometer simultaneous reads each sensor and provides the total field values and automatically calculates the gradient value at that location. The unit is equipped with an electronics console that allows the operator to view and store collected field data in an internal memory.

DATA COLLECTION

Magnetometer survey data was collected at discrete stations from within a 10-by-20 foot rectangular grid established over a 275 by 325 foot survey area at SA 41 (see Figure 22). Total field and vertical gradient data measurements were stored in the magnetometer during the survey day. As mentioned before, a critical aspect of surveying with this geophysical technique is to identify and map potential sources of magnetic interference in a field-drawn sketch map (Figure 23).

A two-person field crew (instrument operator and crew chief) collected magnetometer data on September 9, 1993 during the SSI field program. A survey base stations were established to provide reference points from which to monitor diurnal variations in the magnetic field strength a regular intervals (roughly each hour) during surveying. These values were used later to provide an evaluation of diurnal variations and the need for corrections to the total field data.

At the conclusions of both survey days, data was transferred from the magnetometer's internal memory to a personal computer for processing and interpretation.

DATA PROCESSING AND INTERPRETATION

The natural magnetic field strength variations measured during the 1993 survey day at the base stations was determined not to be significant enough when compared to the observed total field anomaly magnitudes to make necessitate corrections to the data sets.

Data were processed using a geophysical software program with contouring capabilities (GEOSOFT™). The resulting total field and vertical magnetic gradient contour map are presented in Figures 24 and 25, respectively. Magnetic anomalies identified in the contour maps are reviewed and those attributable to surface interference such as bedrock outcrops, metal fences, and ferrous metal debris are noted. The field maps were used during the interpretation process to discriminate between magnetic anomalies caused by natural and cultural surficial features and buried objects.

The majority of total field measurements varied only slightly above and below the mean value of 54,532 gammas over the surveyed area. Extreme values ranging from 52,892 to 55,336 gammas were recorded. Predominant anomalies attributable to cultural interference were observed in the area of the waste material (rusted cans, metal, and glass) monitoring well protective casings, barbed wire fence, former brick kiln structure (reinforcing rods), and numerous piles of metallic debris.

The majority of vertical magnetic gradient values observed in the survey area ranged from -15 to 5 gammas/meter with extreme values ranging from -5666 to 3084 gammas/meter. The mean value for the survey area was -10 gammas/meter. Vertical gradient data did not reveal any other additional significant anomalous areas. Each of the total field anomalies were observable in the vertical gradient data.

TERRAIN CONDUCTIVITY SURVEY

The terrain conductivity survey was conducted using a Geonics™ EM-31 terrain conductivity meter and Polycorder data logger. The EM-31 unit consists of a transmitter/receiver array which can simultaneously measure both components of the electromagnetic magnetic field induced by the instrument when it is coupled to the Polycorder (digital data logger).

DATA COLLECTION

Terrain conductivity data was collected at discrete stations (coincident with the magnetometer survey stations) from within the rectangular grid established over the area that was surveyed at SA 41 in 1993. As with the magnetometer survey, both components of the field measurements were stored with each X and Y grid coordinate.

At the start of each survey day, the survey crew performed set-up procedures as specified in the operations manual. Procedures included battery check, a mechanical "zero" calibration check, and instrument functional checks for phasing and sensitivity. Terrain conductivity measurements collected at stations common to both surveys were very consistent.

At the conclusions of each survey day, data was transferred from the internal memory of the data logger to a personal computer for processing and interpretation.

PROCESSING AND INTERPRETATION

Data collected during the terrain conductivity survey were downloaded from the field data logger to a personal computer and processed using the contouring program mentioned earlier. The resulting quadrature and in-phase component contour maps are presented in Figures 26 and 27, respectively.

Quadrature phase measurements generally varied from 0 to 10 mmhos/meter over the surveyed area. The mean value for the survey area was 4.9 mmhos/meter with extreme values ranging from -53.4 to 17.2. Predominant anomalies attributable to cultural interference were again observed in the area of the waste material, barbed wire fence, former brick kiln structure (reinforcing rods), and to

a lesser extent the monitoring well protective casings and numerous piles of metallic debris. All anomalies were attributable to surface interference observed in the magnetometer survey data.

The in-phase measurements varied roughly ± 1 around a mean value of 0 across the survey area. Extreme values ranging from -31.8 to 14.2 revealed significant anomalies over the debris pile and around the demolished brick kiln. No correlation between the quadrature phase and in-phase data sets was observable. Minor anomalies were observed along wire fences, and other cultural surface features.

FINDINGS AND CONCLUSIONS

Surface exposure of the debris pile is consistent with anomalies in all surveys results suggesting no subsurface extent beyond the surface exposure. A significant amount of ferrous metal (in the form of steel cans) exists in the landfill debris. No major anomalies suggestive of a 55-gallon drum disposal area were observed and no other notable anomalies were observed within the 1993 SSI survey area.
